

Probability Distributions and GAS Models for Realized Covariance Matrices

Michael Stollenwerk

June 7, 2022

Abstract

Realized covariance matrices (RCs) are an important input to assess the risks involved in different investment allocations and it is thus useful to model and forecast them. To this end generalized autoregressive score (GAS) models are employed in this paper. These models are ideal for comparing different probability distributions in terms of their ability to model and forecast RCs, since the dynamic parameters of the conditional observation density are updated by incorporating the shape of the distribution itself (via the scaled score of the log-likelihood). All probability distributions so far applied to time series of RCs in the literature are compared and it is shown how they are related to each other. Furthermore a novel family of probability distribution, which has a property called “tail homogeneity”, is derived and added to the comparison. The necessary inputs for the GAS models (Fisher information matrix and score) are derived for all distributions. An in-sample fit comparison confirms previous results that “fat-tailed” distributions outperform others and shows that the novel distribution family achieves very good fit. Out-of-sample forecasting comparisons further corroborate the excellent performance of the novel distribution family.

Key words: Realized Covariance Matrices, Generalized Autoregressive Score Models, Matrix Distributions

1 Introduction

In recent years there has been a lot of focus on the modeling and forecasting of time-series of realized covariance measures. In this strand of the literature the realized covariance measures are typically treated as “observed” measures of asset price variability, that can be modeled directly (see e.g. Chiriac and Voev 2011, Golosnoy, Gribisch, and Liesenfeld 2012, Opschoor et al. 2018, Gribisch and Stollenwerk 2020). The approach to treat realized measures created from high-frequency price observations as observations of volatility has been pioneered by Andersen et al. 2001 and can be likened to the macroeconomic literature where measurement-error prone variables of interest (e.g. GDP) are also treated as observables and directly modeled.¹ This view allows disregarding any distributional properties of the realized measures that might be inherited from an underlying assumption on the price processes (e.g. semi-martingale) and enables researchers to assume probability distributions on the realized measures directly.

Many different probability distributions with support on realized covariance measures (i.e. symmetric positive semi-definite matrices) have been proposed in the literature. These are the (non-central)-Wishart (Golosnoy, Gribisch, and Liesenfeld 2012, Gorgi et al. 2019, Yu, Li, and Ng 2017), inverse Wishart (Gourieroux, Jasiak, and Sufana 2009, Asai and So 2013), matrix-F (Opschoor et al. 2018, Zhou et al. 2019), Riesz (Gribisch and Hartkopf 2022), inverse Riesz and F-Riesz (both Blasques et al. 2021) distributions. All mentioned distributions are related to each other. The inverse Wishart, inverse Riesz, F and F-Riesz distributions accommodate the loosely defined stylized fact of “fat-tailedness” of realized measures. The recently proposed F-Riesz by Blasques et al. 2021 additionally allows for heterogeneous tails, i.e. it assumes that the variances of the realized variances can differ across assets.

In this paper, we compare, by showing explicitly how they are related to each other, all hitherto used probability distributions ² in terms of their fit to different data sets of time series of realized covariance measures and assess their forecasting performance. Furthermore, we propose a new family of distributions, also related to the other ones mentioned above and included in the comparison, which in contrast to Blasques et al. 2021 assumes tail homogeneity and show that, especially in times of high market

1. See also Andersen et al. 2003, Andersen et al. 2006 and McAleer and Medeiros 2008.

2. Excluding the noncentral Wishart distribution, which gives only slight improvements compared to the Wishart in terms of fit and forecasting ability and is not applicable to dimensions higher than five due to computational difficulties involving the matrix-variate hypergeometric function.

volatility, this distribution represents a more realistic assumption to the data. It is also easier to handle analytically and numerically. It can be rooted in the assumption of a joint t -distribution on the vectors of intra-day returns, which generate realized covariance measures.

The rest of this paper is structured as follows. The next section presents all hitherto used probability distributions and the new family of probability distributions. Section 3 presents the GAS models for all distributions. Section 4 presents the data, Section 5 contains the empirical application. Section 6 concludes.

2 Probability Distributions

Let \mathbf{R} denote a $p \times p$ realized covariance matrix. Any hitherto considered probability distribution can be characterized by its degree of freedom parameter(s), which we denote by $\boldsymbol{\theta}$ and a real symmetric positive semi-definite $p \times p$ parameter matrix $\boldsymbol{\Sigma}$. If its real symmetric positive semi-definite $p \times p$ expected value matrix

$$\mathbb{E}[\mathbf{R}] =: \boldsymbol{\Sigma} = \mathbf{C}\mathbf{C}^\top \quad (1)$$

exists, where \mathbf{C} denotes the lower Cholesky factor, the distribution can be equivalently characterized by $\boldsymbol{\Sigma}$ and $\boldsymbol{\theta}$. In this paper we assume that $\boldsymbol{\Sigma}$ always exists³, such that we can write

$$\mathbf{R} \sim d(\boldsymbol{\Sigma}, \boldsymbol{\theta}), \quad (2)$$

where $d \in (\mathcal{W}, i\mathcal{W}, t\mathcal{W}, it\mathcal{W}, \mathcal{F}, \mathcal{R}, i\mathcal{R}, t\mathcal{R}, it\mathcal{R}, \mathcal{FR}, i\mathcal{FR})$ ⁴ indexes the different distributions. The probability density functions,

$$p_d(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\theta}), \quad (3)$$

3. Existence depends on the degree of freedom parameter(s), but is not a restrictive assumption since for all estimated distributions in this paper, the mean exists.

4. See column 1, table 1 for all considered distributions

for all considered probability distributions are given in table 1. The composition of $\boldsymbol{\theta}$ for each distribution also becomes clear in this table. Finally, let us denote

$$\mathbf{Z} = \mathbf{C}^{-1}\mathbf{R}\mathbf{C}^{-\top} \quad (4)$$

as the standardized realized covariance matrix.

2.1 Stochastic Representations

At the basis of all considered distributions lie the $p \times p$ random triangular matrices

$$\underline{\mathbf{B}} = \begin{bmatrix} \sqrt{\chi_{n_1-1+1}^2} & 0 & \dots & 0 \\ \mathcal{N}(0,1) & \ddots & 0 & \vdots \\ \vdots & \mathcal{N}(0,1) & \ddots & 0 \\ \mathcal{N}(0,1) & \dots & \mathcal{N}(0,1) & \sqrt{\chi_{n_p-p+1}^2} \end{bmatrix} \quad (5)$$

and/or

$$\bar{\mathbf{B}} = \begin{bmatrix} \sqrt{\chi_{\nu_1-p+1}^2} & \mathcal{N}(0,1) & \dots & \mathcal{N}(0,1) \\ 0 & \ddots & \mathcal{N}(0,1) & \vdots \\ \vdots & 0 & \ddots & \mathcal{N}(0,1) \\ 0 & \dots & 0 & \sqrt{\chi_{\nu_p-p+p}^2} \end{bmatrix}, \quad (6)$$

where all random variables inside the matrices are independent of each other ⁵ For the distributions to exist it is thus necessary and sufficient that we restrict $n_i > i - 1$ and $\nu_i > p - i$.⁶ We denote the special cases where for all i , $n_i = n$ with $n > p - 1$ and $\nu_i = \nu$ with $\nu > p - 1$) as $\underline{\mathcal{B}}$ and $\bar{\mathcal{B}}$, respectively.

The stochastic representations of and the relationships between the probability distributions are depicted in figure 1. The t-named distributions are novel distributions that will be explained in more detail in the section 2.2. Note that the stochastic representations in figure 1 are for the mean- \mathbf{I} distributions, that is, all have expectation equal to

5. We choose to name them with the letter “B” due to their resemblance of the “Barlett” decomposition.

6. Note that this does not imply existence of $\mathbb{E}[\mathbf{R}]$. For example the inverse Wishart distribution is based on $(\bar{\mathcal{B}}\bar{\mathcal{B}}^\top)^{-1}$ and its mean only exists if in fact $\nu > p + 1$.

the identity matrix. They have to be pre-multiplied by \mathbf{C} and post-multiplied by \mathbf{C}^\top in order to arrive at the distributions in table 1.

On the vertical axis of figure 1 we can see the number of parameters of the respective distributions. All have $p(p + 1)/2$ distinct parameters in the symmetric positive semi-definite matrix $\mathbf{\Sigma}$ plus the number of degree of freedom parameters. Every Wishart-based distribution is a special case of its Riesz-named counterpart and is obtained by setting the entries in the degree of freedom parameter vector all equal to each other. Furthermore we can see that the (inverse) Riesz and (inverse) Wishart distributions are limiting cases of the other distributions, that have relatively more probability mass on extremely “large” RCs and are thus labeled “fat-tailed”, if we let the parameters governing the “fat-tailedness” go to infinity. Note that the dashed arrows indicate that the distribution at the end of the arrow is not nested by but merely related to the one at the beginning of the arrow.

For each Riesz-named distribution the ordering of the assets in the RCs matters. That is, given an initial ordering, applying a different one to the rows and columns of the RCs and the expected value matrix, as well as to the degree of freedom parameter vectors, changes the probability distribution. This implies that in maximum likelihood estimation, we also have to optimize over the order of the assets, as suggested in Blasques et al. 2021.

Furthermore for all Riesz-named distributions there are two types, one based on \mathbf{B} , the other on $\bar{\mathbf{B}}$. For example the Riesz type II distribution has stochastic representation $\bar{\mathbf{B}}\bar{\mathbf{B}}^\top$ as opposed to $\mathbf{B}\mathbf{B}^\top$ for the Riesz type I distribution. It can however be shown that a Riesz type I distribution is the same as a Riesz type II distribution, where the order of assets in the data matrix and in $\mathbf{\Sigma}$ and in the entries of the parameter vectors are reversed. The same holds for the standardized versions of all distributions.⁷ Thus when optimizing over the asset order, only one of the two types needs to be considered. Finally, note that an inverse F distribution is again an F distribution⁸, but an inverse F-Riesz distribution is not again an F-Riesz distribution.

7. See Theorem 7.2 in the appendix.

8. With the degrees of freedom parameters switched and the expected value matrix inverted, as is easy to see from their stochastic representations.

2.2 The t-Riesz Distribution Family

Recall the stochastic representation for the t-Riesz and the inverse t-Riesz distribution,

$$\frac{\nu - 2}{\nu} \Gamma_{\left(\frac{\nu}{2}, \frac{2}{\nu}\right)}^{-1} \text{dg}(\mathbf{n})^{-\frac{1}{2}} \underline{\mathbf{B}} \underline{\mathbf{B}}^\top \text{dg}(\mathbf{n})^{-\frac{1}{2}} \quad \text{and} \quad \Gamma_{\left(\frac{n}{2}, \frac{2}{n}\right)} \text{dg}(\mathbf{m}^{\text{rR}''})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{rR}''})^{-\frac{1}{2}},$$

respectively. Note that, given $\underline{\mathbf{B}}$ ($\bar{\mathbf{B}}$), a tail realization of the inverse gamma (gamma) distribution yields a tail realization of the t-Riesz (inverse t-Riesz) distribution. This is in stark contrast to the F-Riesz and inverse F-Riesz distribution, which have stochastic representations

$$\text{dg}(\mathbf{m}^{\text{FR}''})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \underline{\mathbf{B}} \underline{\mathbf{B}}^\top \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{FR}''})^{-\frac{1}{2}} \quad \text{and} \quad \text{dg}(\mathbf{m}^{\text{FR}''})^{-\frac{1}{2}} \underline{\mathbf{B}} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \underline{\mathbf{B}}^\top \text{dg}(\mathbf{m}^{\text{FR}''})^{-\frac{1}{2}},$$

respectively. Here, given $\underline{\mathbf{B}}$ ($\bar{\mathbf{B}}$), a tail realization of one of the entries on the main diagonal of $\bar{\mathbf{B}}$ ($\underline{\mathbf{B}}$), while the other diagonal entries do not lie in the tail, yields a tail realization in some of the entries the (inverse) F-Riesz matrix, but has a decreasing effect on the other entries the further away they are from the index where the tail observation occurred. Blasques et al. 2021 call this property of the F-Riesz distribution “tail heterogeneity”, which leads us to calling the t-Riesz distribution family being “tail homogeneous”. The natural conjecture would be that the t-Riesz distribution family might work better in times of market-wide crises, while the F-Riesz distribution has advantages when one asset or subsections of the market are in distress.

The t-Riesz, inverse t-Riesz, inverse t-Wishart and inverse F-Riesz distributions are to the best of my knowledge novel distributions that we derive in the appendix. The t-Wishart distribution is a standardized version of the distribution introduced in Sutradhar and Ali 1989. They prove an interesting result that can be readily applied to the realized covariance estimator, namely that if we assume a joint t-distribution with block diagonal scale matrix, where the blocks are all equal, on all intraday-return vectors, then the realized covariance follows a t-Wishart distribution where the degree of freedom n equals the number of intraday-return vectors. The Wishart distribution can be based on a similar assumption, but with a Normal distribution instead of a t-distribution. As such, the Wishart and t-Wishart distributions are the only ones of the considered distributions for \mathbf{R} , which can be grounded in an assumption on the underlying intraday-return vectors, but it is common knowledge, that the t-distribution assumption is much more realistic than the Normal distribution assumption for return vectors. This is mirrored

in the much superior performance of the t-Wishart compared to the Wishart as will be visible in the empirical part of this paper.

Other advantages of the novel distributions are that they have less parameters than the F(-Riesz) and that their evaluation is numerically more stable as their pdfs depend on the trace, rather than the (power weighted) determinant of \mathbf{Z} .

2.3 Static Estimation

Now lets add subscripts for the days in our sample, $t = 1, \dots, T$. In a first step we will assume a static distribution on the time series of RCs, that is

$$\mathbf{R}_t \stackrel{iid}{\sim} d(\boldsymbol{\Sigma}, \boldsymbol{\theta}), \quad (7)$$

where $\boldsymbol{\Sigma}$ in theory is allowed to differ across distributions. In practice, however, we choose to estimate $\boldsymbol{\Sigma}$ with the obvious method of moments estimator to avoiding the curse of dimensionality for large cross-sections,

$$\hat{\boldsymbol{\Sigma}} = \frac{1}{T} \sum_{t=1}^T \mathbf{R}_t, \quad (8)$$

which of course is the same across distributions. Then, in a second step we estimate the degrees of freedom parameters via standard numerical maximum likelihood estimation, conditional on our estimate for $\boldsymbol{\Sigma}$. I follow the algorithm proposed in Blasques et al. 2021 to optimize over the asset ordering. The seed for the random generation of permutations to try, is the same for all Riesz-named distributions.

3 GAS Models

In the literature on time series of RCs it is standard to assume time-variation in the mean, i.e. in the $\boldsymbol{\Sigma}$ matrix of the underlying distribution, while leaving the degree of freedom parameters fixed over time, that is

$$\mathbf{R}_t | \mathbb{F}_{t-1} \sim d(\boldsymbol{\Sigma}_t, \boldsymbol{\theta}), \quad (9)$$

where \mathbb{F}_{t-1} represents all information up to time $t - 1$. There are different proposals for the updating mechanism of $\boldsymbol{\Sigma}_t$ in the literature. For example one could simply

assume a multivariate GARCH(1,1)-type recursion, $\boldsymbol{\Sigma}_t = \boldsymbol{\Xi} + a\mathbf{R}_{t-1} + b\boldsymbol{\Sigma}_{d,t-1}$, where $\boldsymbol{\Xi}$ is a symmetric positive semi-definite $p \times p$ parameter matrix. A natural choice for the updating mechanism in order to compare different probability distributions is the Generalized Autoregressive Score (GAS) framework introduced by Creal, Koopman, and Lucas 2013 and Creal, Koopman, and Lucas 2011, because it incorporates directly information about the shape of the distributions into the updating process. The first example of such a model applied to time-series of RCs is given by Gorgi et al. 2019, who apply the GAS framework to a Wishart distribution on a set of two-dimensional time series of RCs. The standard recursion in a GAS framework is

$$\boldsymbol{\Sigma}_t = (1 - b)\boldsymbol{\Xi} + a\mathbf{S}_{d,t-1} + b\boldsymbol{\Sigma}_{d,t-1}, \quad (10)$$

where \mathbf{S}_t is the scaled score of the assumed probability distribution d at time t . One popular choice for the scaling of the score,

$$\nabla_t = \frac{\partial \log p_d(\boldsymbol{\Sigma}_t, \boldsymbol{\theta})}{\partial \text{vech}(\boldsymbol{\Sigma}_t)}, \quad (11)$$

is the inverse of the Fisher information matrix,

$$\mathcal{I}_t = -\mathbb{E} \left[\frac{\partial \log p_d(\boldsymbol{\Sigma}_t, \boldsymbol{\theta})}{\partial \text{vech}(\boldsymbol{\Sigma}_t)} \frac{\partial \log p_d(\boldsymbol{\Sigma}_t, \boldsymbol{\theta})}{\partial \text{vech}(\boldsymbol{\Sigma}_t)^\top} \right], \quad (12)$$

such that

$$\mathbf{S}_t = \text{ivech}(\mathcal{I}_t^{-1} \nabla_t), \quad (13)$$

where p_d represents the probability density function of distribution i . In this paper we derive the scores ∇_t and Fisher information matrices \mathcal{I}_t for all probability distributions⁹ considered above. These can be found, omitting the subscripts, in table 2 and 3, respectively.

Unfortunately, the Fisher information matrices of Riesz-named distributions involve matrix multiplications and inversions of $p^2 \times p^2$ matrices, which causes computation of the scaled scores in equation (13) to be prohibitively slow for estimation of GAS models of dimension say $p > 10$. Luckily, the most important part of the scaled scores

9. Except for the Fisher information matrix of the (inverse) F-Riesz distribution.

are the scores themselves, which at time t define the steepest ascend direction of the log-likelihood, in which the parameters should be updated. The scaling is of secondary importance. If we scale the Riesz-named distribution scores with the Fisher information matrices of their Wishart-based counterparts, i.e. we set all parameters in a degree of freedom parameter vector equal to the average, then theorem 3.1 shows that the computation of \mathbf{S}_t reduces to $p \times p$ matrix operations for all distributions.¹⁰

Theorem 3.1. *Consider, omitting the subscript t ,*

$$\mathbf{S} = \text{ivech}(\mathcal{I}^{-1}\nabla), \quad (14)$$

as defined in equation (13). For any Riesz-named distribution use \mathcal{I} of its Wishart-based counterpart instead of its own, by setting the degree(s) of freedom equal to the average of the corresponding degree of freedom parameter vector(s). Then

$$\mathbf{S} = \frac{\alpha_{\boldsymbol{\theta}}}{2} \boldsymbol{\Sigma} (\Delta + \Delta^\top) \boldsymbol{\Sigma} + \beta_{\boldsymbol{\theta}} \text{tr}(\boldsymbol{\Sigma}\Delta) \boldsymbol{\Sigma}, \quad (15)$$

where Δ is the score matrix w.r.t. $\boldsymbol{\Sigma}$, ignoring symmetry,¹¹ and α and β depend only on the degree of freedom parameters of the respective distribution.

Proof. Note that \mathcal{I} of all Wishart-based have the form

$$\mathcal{I} = \mathbf{G}^\top \left(\alpha_{\boldsymbol{\theta}} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + c_{\boldsymbol{\theta}} \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \mathbf{G}, \quad (16)$$

where the scalars $\alpha_{\boldsymbol{\theta}}$ and $c_{\boldsymbol{\theta}}$ only depend on the degree of freedom parameter(s) of the respective distribution. Thus, using Theorem 7.5 we have

$$\mathcal{I}^{-1} = \alpha_{\boldsymbol{\theta}} \left(\mathbf{G}^\top \left[(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \alpha_{\boldsymbol{\theta}}^{-1} c_{\boldsymbol{\theta}} \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right] \mathbf{G} \right)^{-1} \quad (17)$$

$$= \alpha_{\boldsymbol{\theta}} \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha_{\boldsymbol{\theta}}^{-1} c_{\boldsymbol{\theta}}}{1 + \alpha_{\boldsymbol{\theta}}^{-1} c_{\boldsymbol{\theta}} p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}^+ \quad (18)$$

$$= \mathbf{G}^+ \left(\alpha_{\boldsymbol{\theta}} \boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha_{\boldsymbol{\theta}} c_{\boldsymbol{\theta}}}{\alpha_{\boldsymbol{\theta}} + c_{\boldsymbol{\theta}} p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}^+. \quad (19)$$

10. Apart from making the GAS models applicable to high dimensions this also circumvents the difficulties of obtaining the F-Riesz Fisher information matrix as its Wishart-based nested version has been derived in this paper.

11. $\nabla = \frac{\partial \log p(\boldsymbol{\Sigma}, \boldsymbol{\theta})}{\partial \text{vec}(\boldsymbol{\Sigma})^\top} \frac{\partial \text{vec}(\boldsymbol{\Sigma})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \text{vec}(\Delta)^\top \mathbf{G} \Rightarrow \Delta = \text{ivec} \left(\frac{\partial \log p(\boldsymbol{\Sigma}, \boldsymbol{\theta})}{\partial \text{vec}(\boldsymbol{\Sigma})^\top} \right) = \frac{\partial \log p(\boldsymbol{\Sigma}, \boldsymbol{\theta})}{\partial \boldsymbol{\Sigma}}$

Define $\beta_{\boldsymbol{\theta}} = \frac{\alpha_{\boldsymbol{\theta}} c_{\boldsymbol{\theta}}}{\alpha_{\boldsymbol{\theta}} + c_{\boldsymbol{\theta}} p}$,

$$\mathbf{G}^+ \left(\alpha_{\boldsymbol{\theta}} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \beta_{\boldsymbol{\theta}} \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) (\mathbf{G}^+)^{\top} \mathbf{G}^{\top} \text{vec}(\Delta) \quad (20)$$

$$\stackrel{(74)}{=} \mathbf{G}^+ \left(\alpha_{\boldsymbol{\theta}} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \beta_{\boldsymbol{\theta}} \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \text{vec}(\Delta) \quad (21)$$

$$= \alpha_{\boldsymbol{\theta}} \mathbf{G}^+ (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) \text{vec}(\Delta) + \beta_{\boldsymbol{\theta}} \mathbf{G}^+ \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \text{vec}(\Delta) \quad (22)$$

$$= \alpha_{\boldsymbol{\theta}} \mathbf{G}^+ \text{vec}(\boldsymbol{\Sigma} \Delta \boldsymbol{\Sigma}) + \beta_{\boldsymbol{\theta}} \text{tr}(\boldsymbol{\Sigma} \Delta) \mathbf{G}^+ \text{vec}(\boldsymbol{\Sigma}) \quad (23)$$

$$= \frac{\alpha_{\boldsymbol{\theta}}}{2} \text{vech} \left(\boldsymbol{\Sigma} (\Delta + \Delta^\top) \boldsymbol{\Sigma} \right) + \beta_{\boldsymbol{\theta}} \text{tr}(\boldsymbol{\Sigma} \Delta) \text{vech}(\boldsymbol{\Sigma}) \quad (24)$$

$$= \text{vech} \left(\frac{\alpha_{\boldsymbol{\theta}}}{2} \boldsymbol{\Sigma} (\Delta + \Delta^\top) \boldsymbol{\Sigma} + \beta_{\boldsymbol{\theta}} \text{tr}(\boldsymbol{\Sigma} \Delta) \boldsymbol{\Sigma} \right). \quad (25)$$

Now simply apply the *ivech* operator. \square

Using Theorem 3.1 in the standard GAS recursion (10) and we arrive at

$$\boldsymbol{\Sigma}_t = (1 - b) \boldsymbol{\Xi} + a \frac{\alpha_{\boldsymbol{\theta}}}{2} \boldsymbol{\Sigma}_t \left(\Delta_t + \Delta_t^\top \right) \boldsymbol{\Sigma}_t + a \beta_{\boldsymbol{\theta}} \text{tr}(\boldsymbol{\Sigma} \Delta_t) \boldsymbol{\Sigma}_t + b \boldsymbol{\Sigma}_{t-1}. \quad (26)$$

From here it is a small cost to further generalize the model to

$$\boldsymbol{\Sigma}_t = (1 - c) \boldsymbol{\Xi} + a \boldsymbol{\Sigma}_t \left(\Delta_t + \Delta_t^\top \right) \boldsymbol{\Sigma}_t + b \text{tr}(\boldsymbol{\Sigma} \Delta_t) \boldsymbol{\Sigma}_t + c \boldsymbol{\Sigma}_{t-1}, \quad (27)$$

where a , b and c are now stand-alone parameters, independent of the degree of freedom parameters. Equation (27) is the recursion we choose in all our empirical applications.

For “fat-tailed” distributions GAS models down-weight the impact of extreme realizations of \mathbf{R}_t on the updating process of $\boldsymbol{\Sigma}_t$, since extreme realizations of \mathbf{R}_t are less unexpected by a model with a “fat-tailed” distribution and thus yield less extreme scaled score realizations \mathbf{S}_t . This type of modeling behavior has also been advocated for in the literature by e.g. Bollerslev, Patton, and Quaadvlieg 2018, whos “Dynamic Attenuation Model” down-weights the impact of extreme realizations by incorporating the fact that they are relatively more inaccurate estimates of integrated covariance, “endogenously shrinking the influence of past realized covariances based on dynamically varying weights determined by an estimate of the reliability of the realized covariances”.

As a final interesting point it holds that when we scale the (inverse) Riesz or Wishart distributions by their inverse Fisher information matrix, we obtain simple the GARCH-

type dynamics mentioned before.¹²

3.1 Mixture Model

As mentioned before, an important difference between the F-Riesz distribution and the (inverse) t-Riesz distribution is the tail behavior, i.e. tail-homogeneity versus tail-heterogeneity. To shed some light onto this issue we introduce a GAS mixture model between the F-Riesz and inverse t-Riesz distribution,¹³ where the weights are allowed to vary over time. The conjecture is that during times of crises, a higher weight is estimated in the tail-homogeneous inverse t-Riesz distribution, while in calm time the weight on the tail-heterogeneous F-Riesz distribution is relatively higher.

In particular, the probability density function of the mixture distribution obtains as

$$p_{mix}(\mathbf{R}_t | \boldsymbol{\Sigma}_t, \mathbf{n}_1, \nu_1, \mathbf{n}_2, \nu_2) = \lambda_t p_{itR}(\mathbf{R}_t | \boldsymbol{\Sigma}_t, \mathbf{n}_1, \nu_1) + (1 - \lambda_t) p_{FR}(\mathbf{R}_t | \boldsymbol{\Sigma}_t, \mathbf{n}_2, \nu_2). \quad (28)$$

A further advantage of the GAS model framework is that it provides a generic method to make any distributional parameter time-varying, which is especially valuable in cases where an obvious intuitive updating mechanism is not available, like for the weights of a mixture distribution,¹⁴ which has been proposed by Catania 2021. We assume

$$\lambda_{t+1} = (1 - b_\lambda)\xi + a_\lambda s_t + b_\lambda \lambda_t, \quad (29)$$

where s_t is the scaled score of the mixture distribution w.r.t. λ_t . The score w.r.t. the weight of a mixture distribution provides a very intuitive way of updating the weights since it equals

$$\frac{\partial \log p_{mix}(\cdot)}{\partial \lambda_t} = \frac{p_{itR}(\cdot) - p_{FR}(\cdot)}{\lambda_t p_{itR}(\cdot) + (1 - \lambda_t) p_{FR}(\cdot)} = \frac{p_{itR}(\cdot) - p_{FR}(\cdot)}{p_{mix}(\cdot)}. \quad (30)$$

That is whenever the inverse t-Riesz distribution obtained a higher likelihood value in time t than the F-Riesz distribution, its weight increases in $t + 1$ and vice-versa. When p_{itR} (p_{FR}) goes to zero or infinity, $\frac{\partial \log p_{mix}(\cdot)}{\partial \lambda_t}$ goes to 1 or $1/(1 - \lambda_t)$ (-1 or $1/\lambda_t$), which

12. See appendix.

13. The F-Riesz and inverse t-Riesz distributions turn out to be close competitors in terms of fit, the t-Riesz does not provide an as good fit.

14. As opposed to the updating equation of $\boldsymbol{\Sigma}_t$ (10), where an immediately obvious alternative might be to replace the score with \mathbf{R}_{t-1} .

implies that

$$-\frac{1}{1-\lambda_t} \leq \frac{\partial \log p_{mix}(\cdot)}{\partial \lambda_t} \leq \frac{1}{\lambda_t}. \quad (31)$$

In order to stabilize the score, we want to ensure that it always lies on an interval of length one, thus we multiply with the inverse of the interval length

$$\left(\frac{1}{\lambda_t} + \frac{1}{1-\lambda_t}\right)^{-1} = \lambda_t - \lambda_t^2, \quad (32)$$

to obtain the scaled score

$$s_t = (\lambda_t - \lambda_t^2) \frac{\partial \log p_{mix}(\cdot)}{\partial \lambda_t}, \quad (33)$$

with

$$-\lambda_t \leq s_t \leq 1 - \lambda_t, \quad (34)$$

thus

$$-1 \leq s_t \leq 1. \quad (35)$$

The score and especially the Fisher information matrix of the mixture model w.r.t. Σ_t are much more complicated, which is why in order to nest the GAS models based on the FRiesz and inverse t-Riesz distribution we choose to base our GAS dynamics on the scaled scores of the FRiesz and inverse t-Riesz model

$$\Sigma_t = (1-c)\Xi + a \Sigma_t \left[\lambda_t \left(\nabla_{itR,t} + \nabla_{itR,t}^\top \right) (1-\lambda_t) \left(\nabla_{FR,t} + \nabla_{FR,t}^\top \right) \right] \Sigma_t \quad (36)$$

$$+ b \operatorname{tr}(\Sigma(\lambda_t \nabla_{itR,t} + (1-\lambda_t) \nabla_{FR,t})) \Sigma_t + c \Sigma_{t-1}. \quad (37)$$

3.2 Estimation of the GAS Models

Since $\mathbb{E}[\mathbf{S}_t] = \mathbf{0}$, it is easy to show that for equation (10) it holds that

$$\mathbb{E}[\mathbf{R}_t] = \Xi. \quad (38)$$

We thus choose the well established two step estimation method where we “target” Ξ in the first step, that is we simply apply the obvious method of moments estimator for it

$$\hat{\Xi} = \frac{1}{T} \sum_{t=1}^T \mathbf{R}_t, \quad (39)$$

and we estimate a , b and the degree of freedom parameters in a second step via standard numerical maximum likelihood estimation, conditional on our estimate for Ξ in the first step. Again, we follow the algorithm proposed in Blasques et al. 2021 to optimize over the asset ordering, where the two-step maximum likelihood estimation described above, goes into step 2 of their 4-step estimation algorithm. In the mixture model of subsection 3.1 we include ξ , a_λ , b_λ and λ_1 in the second step maximum likelihood estimation.

4 Data

Our original data are one-minute close prices from all trading days from 1 January 1998 to 13 March 2020 for every stock that was a constituent of the S&P 500 index during the sample period. A close price is defined as the latest observed trade price of the respective one-minute interval and as such is we have previous tick interpolation on a fixed one-minute grid. We acquired the data from Quantquote¹⁵, who combine, clean and process data directly obtained different exchanges, where the biggest are NYSE, NASDAQ and AMEX¹⁶. The data include observations from official trading hours as well as before- and after hour trading observations.

The aim is to produce the longest possible time series of accurately estimated daily integrated covariance estimators. We exclude dates before 1 January 2002, because the NYSE fully implemented decimal pricing in 2001¹⁷ and there are numerous other trading irregularities during this year¹⁸. This leaves 4808 trading days. To be consistent across trading days we only keep observations from official trading hours. We then exclude all stocks that on at least one of the remaining trading days have missing observations on

15. The company is recommended by the Caltech Quantitative Finance Group, see <http://quant.caltech.edu/historical-stock-data.html>.

16. AMEX was bought by NYSE in 2008, and handled only 10% of trades at its height

17. On 29 January 2001 to be precise.

18. e.g. the days surrounding the terrorist attacks on 11 September 2001 and ”computer systems connectivity problems” on 8 June 2001.

more than 25% minutes. From an initial sample of 983 stocks this leaves 99 stocks.¹⁹ Excluding illiquid stocks is common practice in creating time-series of integrated covariance estimators (see e.g. Lunde, Shephard, and Sheppard 2016). While this procedure biases the sample towards stocks which were very liquid over the entire sample period²⁰ it does ensure that for those stocks included the integrated covariance estimates are accurate.

I follow Opschoor et al. 2018 and Blasques et al. 2021 and construct realized covariance matrices of the 99 assets using five-minute returns with subsampling²¹. Then we randomly choose two 5- and 10-dimensional principal submatrices and one 25- and 50-dimensional principal submatrix for a total of six datasets.

5 Empirical Application

In this section we estimate the static distributions and GAS models based all distributions to the data described above.

5.1 In-Sample Fit

Notice, as is easily seen from the stochastic representations, that for $c > 0$,

$$\mathbf{R} \sim d(\boldsymbol{\Sigma}, \boldsymbol{\theta}) \Leftrightarrow c\mathbf{R} \sim d(c\boldsymbol{\Sigma}, \boldsymbol{\theta}). \quad (40)$$

From table 1 it is however obvious that, since \mathbf{Z} is unaffected, the scaling with c changes the probability density functions of all distributions by the same amount through the term $|\mathbf{R}|^{-(p+1)/2}$. That is, for a different scaling of the RCs²² the overall log-likelihoods of all distributions differ by a factor of $Tp(p+1)/2 \log(c)$, which obviously has an impact on relative comparisons between log-likelihood and information criterion values. For this reason the part of the log-likelihoods and information criteria that are due to $|\mathbf{R}|^{-(p+1)/2}$ are displayed separately in tables 4 and 6.

It is no surprise that distributions that are nested by others²³ obtain a lower log-

19. 465 are left after excluding those that do not have an observation at all on at least one trading day.

20. Relatively young firms (e.g. Facebook or Tesla) are excluded.

21. The subsampling estimator was first proposed by Zhang, Mykland, and Ait-Sahalia 2005

22. For example some researches like to scale in terms of annualized volatility in percentage terms, i.e. $c = 252 * 100 * 100$ relative to trading-daily volatility.

23. see again figure 1

likelihood value than the nesting ones. It is however not clear how big the differences are and how non-nested distributions, e.g. the (inverse) F-Riesz and the (inverse) t-Riesz distributions compare. In table 4 (5) we see the log-likelihood (Bayes information criterion) values of the estimated static distributions, table 6 (7) displays the log-likelihood (Bayes information criterion) values of the estimated GAS models for the different datasets. Note that the Bayes information criterion (BIC) rankings and distances are very close to those of the log-likelihood, since the BIC penalty term for the number of parameters is dominated by the number of parameters in Σ , which is common to all distributions and are of order n^2 .

In the static setting we see a clear pattern in favor of the t-named distributions and the (inverse) F-Riesz distribution. The best fit is achieved by the tail homogeneous inverse t-Riesz distribution for all datasets.

In the dynamic GAS setting the picture is less clear. It is apparent that the mean shifting achieved by time-variation in Σ_t drastically improves the fit as compared to the static setting for all distributions. It stands out that the inverse t-Riesz and F-Riesz distributions achieve the best fit and are very close to each other. The former achieves the best fit for four datasets and the latter for one dataset. Thus, once we have accounted for the time-varying mean, it seems that the difference between “tail homogeneity” and “tail heterogeneity” are slim.

5.1.1 Tail Homogeneity vs Tail Heterogeneity

Now we investigate a bit further the differences in fit between the inverse t-Riesz and the F-Riesz distribution. Figure 2 shows the difference in log-likelihood contributions between the two distributions depending on the log determinant of the RDs for the first five-dimensional dataset. We clearly see, that the inverse t-Riesz distribution gains its advantage in static fit mainly from the “larger” RCs. This is in line with our expectation that tail heterogeneity is disadvantageous for crises periods. Surprisingly, it also fits better for very small RCs.

As we see in figure 3, as soon as we introduce dynamics in Σ , the clear advantage of the inverse t-Riesz disappears although there still seems to be a relationship between bigger RCs being better captured by the inverse t-Riesz distribution, especially for the largest RCs. It seems that mean shifting dynamics of the GAS models do a very good job at .

Finally a look at our estimated mixture model weights in figure 4 for e.g. the first five-dimensional dataset reveals that, when we allow the model to choose the weights between the inverse t-Riesz and the F-Riesz distribution, it tends to put a higher weight on the inverse t-Riesz distribution in times of large RCs, as we expected.

5.2 Out-of-Sample Forecasting Ability

I use the 10-dimensional dataset and starting from 2007 re-estimate the GAS models for the different distributions daily with a moving window of 1250 (roughly 5 years) trailing observations, make one-day ahead forecasts and evaluate the forecasting ability with three different loss functions. For the Riesz-named distributions we do not optimize over the ordering of the assets, but simply take the optimal ordering of the full-sample estimations in table 6. Note that the forecasted $\widehat{\Sigma}_{t+1}$ is easy to get by simply plugging \mathbf{R}_t and $\widehat{\Sigma}_t$, which is obtained from the estimation, into equation (10).

The first loss function is the simple mean squared error. The second one is the log-score, where \mathbf{R}_{t+1} is plugged into the time- t forecasted log probability density function,

$$\log p_d(\mathbf{R}_{t+1} | \widehat{\Sigma}_{t+1}, \widehat{\boldsymbol{\theta}}; \mathcal{F}_t).$$

For the third loss-function we want to minimize portfolio variance, which is an economically relevant objective as is seen by a quick search through Morningstar listed US equity funds, which yields a total of 14 volatility related funds, see table 15. For this we take the interpretation that $\widehat{\Sigma}_{t+1}$ is the predicted RC and we want to minimize the predicted portfolio variance

$$\mathbf{R}\mathbf{V}_{t+1}^{pred} = \mathbf{w}_{t+1}^\top \widehat{\Sigma}_{t+1} \mathbf{w}_{t+1}.$$

To do so an investor must set optimal portfolio weights

$$\mathbf{w}_{t+1}^* = \frac{\left(\widehat{\Sigma}_{t+1}\right)^{-1} \mathbf{1}}{\mathbf{1}^\top \left(\widehat{\Sigma}_{t+1}\right)^{-1} \mathbf{1}}.$$

The actually realized portfolio variance

$$\left(\mathbf{w}_{t+1}^*\right)^\top \mathbf{R}_{t+1} \mathbf{w}_{t+1}^* \tag{41}$$

is then the loss for $t + 1$.²⁴

We evaluate the predictive ability by constructing model confidence sets as proposed in Hansen, Lunde, and Nason 2011. These sets contain the model with the best predictive ability for a given confidence level.

Table 11 shows the results of this forecasting exercise. First of all it is striking to see that the inverse t-Riesz distribution has the lowest loss for all loss-function-dataset combinations except one. Furthermore, it is contained in the 90% model confidence set in all loss-function-dataset combinations except two. Finally, if we restrict the forecasting sample to the volatile market window from 01 January 2007 to 31 December 2010, then table 12 reveals that it is clearly preferred in terms of forecasting performance to the benchmark model, the F-Riesz distribution.

6 Conclusion

In this paper all probability distributions so far applied to time series of RCs in the literature are compared and it is shown how they are related to each other. A novel family of probability distribution, which has an intuitive property called “tail homogeneity”, is derived and added to the comparison. Generalized autoregressive score (GAS) models are derived for all distributions. The empirical application shows a similar fit of some of the novel distributions to the so-far best competitor distribution, the F-Riesz. The finding of Blasques et al. 2021 that there is “strong heterogeneity of tail behavior of realized covariance matrices” cannot be confirmed, as the “tail-homogeneous” inverse t-Riesz distribution has similar fit and forecasting performance to the F-Riesz distribution. In a portfolio risk minimizing the novel distribution family performs significantly better than all other distributions.

Table 1: Probability density functions of all considered distributions. Recall that $\mathbf{Z} = \mathbf{C}^{-1}\mathbf{R}\mathbf{C}^{-\top}$, where \mathbf{C} is the lower Cholesky factor of $\boldsymbol{\Sigma}$. The degrees of freedom parameters: $\mathbf{n} = (n_1, n_2, \dots, n_p)^\top$ and $\boldsymbol{\nu} = (\nu_1, \nu_2, \dots, \nu_p)^\top$ are real parameter vectors, n and ν are scalars. A bar on top of a vector denotes the average of its entries, e.g. $\bar{\mathbf{n}} = p^{-1}\sum_{i=1}^p n_i$, left arrow on top of a vector denotes the original vector in reverse order, e.g. $\overleftarrow{\mathbf{n}} = (n_p, n_{p-1}, \dots, n_1)^\top$. The well known gamma function $\Gamma(\cdot)$, the multivariate gamma function $\Gamma_p(\cdot)$ and $\Gamma_p(\cdot)$ with scalar argument are defined in equations (5.2.1), (35.3.5) and (35.3.6) of the NIST Digital Library of Mathematical Functions, respectively. The determinant with subscript, e.g. $|\mathbf{Z}|_{\frac{\mathbf{n}}{2}}$, denotes the power weighted determinant as in Blasques et al. 2021, also know as highest weight vector or generalized power function. For the definition of \mathbf{m}^{r_i} , \mathbf{m}^{r_i} and \mathbf{m}^{r_i} see equations (292), (462) and (486), respectively. See the appendix for further information and derivations.

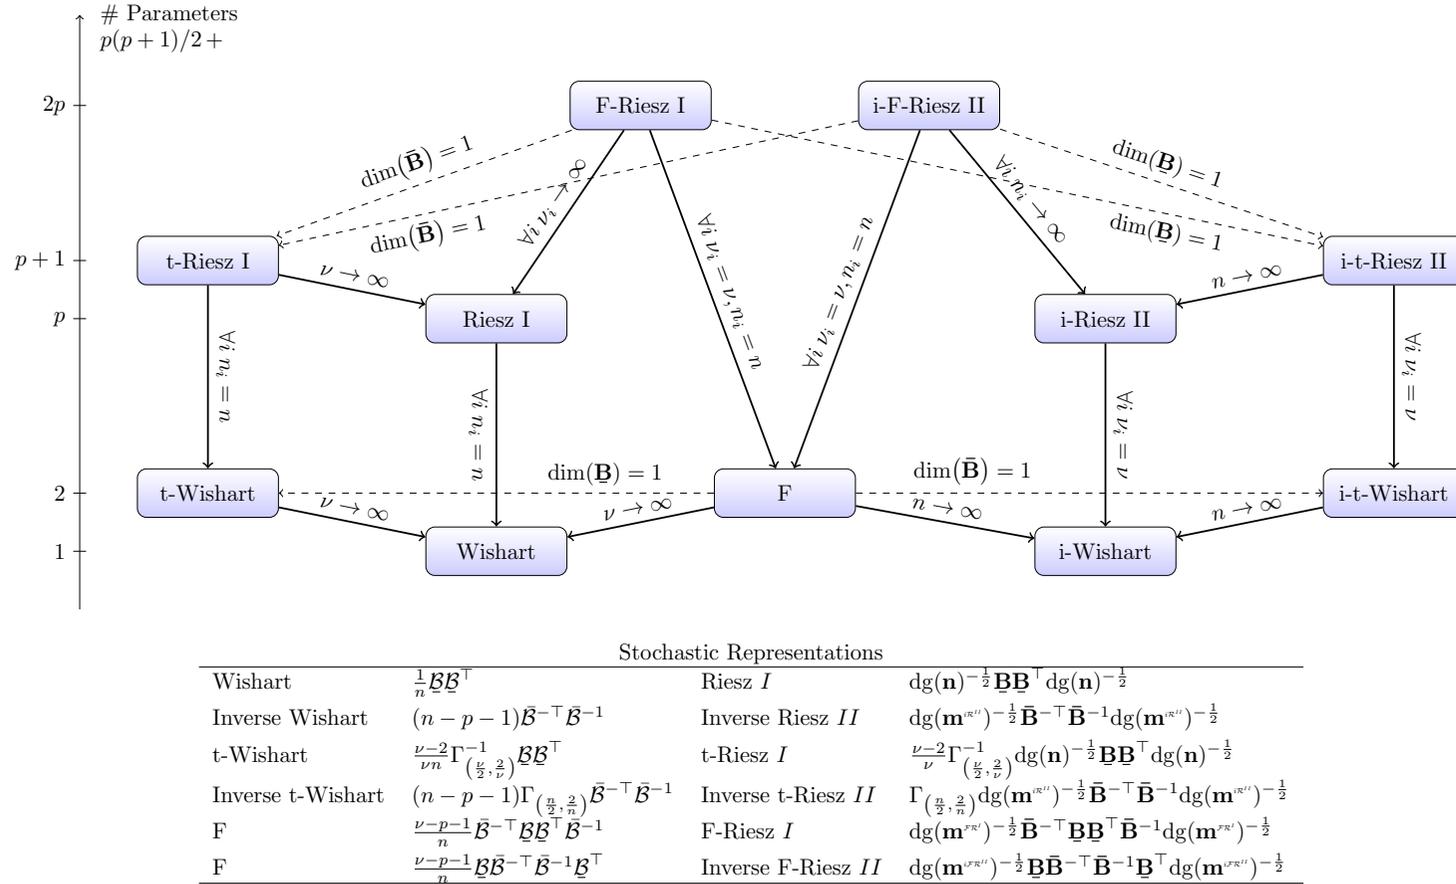

Figure 1: Stochastic representations and the relationships between the considered probability distributions. Every arrow indicates a generalization, where the distribution further down is a nested by the one further up. The dashed arrows indicate a relation, where the distribution at the end of the arrow is related to but not nested by the other one. Note that the stochastic representations are for the distributions with expectation equal to the identity matrix. They have to be pre-multiplied by \mathbf{C} and post-multiplied by \mathbf{C}^\top in order to arrive at the general standardized distributions as in table 1.

Distribution	Score, $\nabla = \mathbf{G}^\top \text{vec}(\Delta)$
Wishart	$\frac{1}{2} \mathbf{G}^\top \text{vec} (n \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1})$
Inverse Wishart	$-\frac{1}{2} \mathbf{G}^\top \text{vec} ((\nu - p - 1) \mathbf{R}^{-1} - \nu \boldsymbol{\Sigma}^{-1})$
t-Wishart	$\frac{1}{2} \mathbf{G}^\top \text{vec} \left(n \frac{\nu + pn}{\nu - 2 + n \text{tr}(\boldsymbol{\Sigma}^{-1} \mathbf{R})} \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1} \right)$
Inverse t-Wishart	$-\frac{1}{2} \mathbf{G}^\top \text{vec} \left(\frac{(n + p\nu)(\nu - p - 1)}{n + (\nu - p - 1) \text{tr}(\boldsymbol{\Sigma} \mathbf{R}^{-1})} \mathbf{R}^{-1} - \nu \boldsymbol{\Sigma}^{-1} \right)$
F	$-\frac{1}{2} \mathbf{G}^\top \text{vec} \left((n + \nu) \left(\boldsymbol{\Sigma} + \frac{n}{\nu - p - 1} \mathbf{R} \right)^{-1} - \nu \boldsymbol{\Sigma}^{-1} \right)$
Riesz	$\mathbf{G}^\top \text{vec} (\mathbf{C}^{-\top} \Phi (\mathbf{C}^\top \text{tril} (\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}))) \mathbf{C}^{-1})$
Inverse Riesz	$-\mathbf{G}^\top \text{vec} (\mathbf{C}^{-\top} \Phi (\mathbf{C}^\top \text{tril} (\mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{\text{r}i})^{-1} - \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}))) \mathbf{C}^{-1})$
t-Riesz	$\mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\frac{\nu + p\bar{n}}{\nu - 2 + \text{tr}(\text{dg}(\mathbf{n}) \mathbf{Z})} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \right) \right) \mathbf{C}^{-1} \right)$
Inverse t-Riesz	$-\mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\frac{n + p\bar{\nu}}{n + \text{tr}(\text{dg}(\mathbf{m}^{\text{r}i})^{-1} \mathbf{Z}^{-1})} \mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{\text{r}i})^{-1} - \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) \right) \right) \mathbf{C}^{-1} \right)$
F-Riesz	$\mathbf{G}^\top \text{vec} (\mathbf{C}^{-\top} \Phi (\mathbf{C}^\top \text{tril} (\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) - \mathbf{C}_{\mathbf{B}}^{-\top} \text{dg}(\boldsymbol{\nu} + \mathbf{n}) \mathbf{C}_{\mathbf{B}}^{-1} \text{Cdg}(\mathbf{m}^{\text{r}i})^{-1})) \mathbf{C}^{-1})$
Inverse F-Riesz	$-\mathbf{G}^\top \text{vec} (\mathbf{C}^{-\top} \Phi (\mathbf{C}^\top \text{tril} (\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) - \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{\text{r}i}) \mathbf{C}^{-1} \mathbf{C}_{\mathbf{B}_2} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{\mathbf{B}_2}^\top \mathbf{C}^{-\top})) \mathbf{C}^{-1})$

Table 2: Scores w.r.t. $\boldsymbol{\Sigma}$ of all considered distributions. The subscripts are omitted for readability. \mathbf{G} denotes the duplication matrix. $\mathbf{C}_{\mathbf{B}}$ denotes the lower Cholesky factor of $\mathbf{B} = \mathbf{C} \text{dg}(\mathbf{m}^{\text{r}i})^{-1} \mathbf{C}^\top + \mathbf{R}$. $\mathbf{C}_{\mathbf{B}_2}$ denotes the lower Cholesky factor of $\mathbf{B}_2 = (\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{\text{r}i})^{-1} \mathbf{C}^{-1} + \mathbf{R}^{-1})^{-1}$. The $\text{tril}(\mathbf{X})$ function returns a lower triangular matrix by setting all elements of \mathbf{X} above the main diagonal equal to zero, the $\Phi(\mathbf{X})$ function is defined in 7.2. It returns a lower triangular matrix by setting all elements of \mathbf{X} above the main diagonal equal to zero and halving the entries on the main diagonal. See the appendix for the derivations.

Distribution	Fisher Information Matrix \mathcal{I}
Wishart	$\frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}$
Inverse Wishart	$-\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}$
t-Wishart	$\frac{n}{2} \mathbf{G}^\top \left(\frac{\nu + pn}{\nu + pn + 2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{n}{(\nu + pn + 2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}$
Inverse t-Wishart	$-\frac{\nu}{2} \mathbf{G}^\top \left(\frac{n + p\nu}{n + p\nu + 2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{\nu}{(n + p\nu + 2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}$
F	$\frac{1}{2} \mathbf{G}^\top \left((\nu + (n + \nu)(c_3 + c_4)) (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + (n + \nu)c_4 \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}$

Table 3: Fisher information matrices of all considered Wishart-based distributions. The subscripts i and t are omitted for readability. \mathbf{G} denotes the duplication matrix. For the derivations and the definitions of c_3 and c_4 see equations (568) and (567), respectively. The Fisher information matrices of the (inverse) Riesz and t-Riesz distributions are derived in the appendix as well.

7 Appendix

7.1 Feedback

Anne Opschoor:

- Clearer Motivation, clearer view of contributions, more advertising. More clear empirical contribution, maybe more focus on differences between t-named and FRiesz.
- Maybe Calm/Volatile period split of sample to clearer see t-named advantage.
- Likes weight idea, more focus on it.

Timo Dimitriadis:

- Diagonal GAS structure
- MSE als Loss anschauen. Eigentlich, meint er, mache ich keine Verteilungsvorhersagen, sondern nur mean vorhersagen Σ_{t+1} , da wäre MSE angemessener. Wenn t-basiert nicht besser ist, kann ich sagen, hey aber wir machen doch bessere Verteilungsvorhersagen, wenn besser ist, kann ich sagen, hey on top machen wir auch noch Verteilungsvorhersagen.

HKMetrics participant:

- Compare distribution of largest and smallest eigenvalues in ?data? with the ones (simulated, if not available) from the different distributions, for some reason.

Christian Conrad:

- Ist es so, dass für größer werdendes p , die Kovarianzen immer wichtiger werden für die logdeterminant (der Daten)? -j Implikation muss ich mir noch Gedanken machen.
- Percentage decreases in realized volatility in last table to make more prominent the improvement.
- MCS anschauen

7.2 To-Do

- **Get this document to be a submittable paper.**
- The inverse of a covariance matrix is sometimes called *concentration matrix* or *precision matrix*. It is directly related to the *partial correlations*. See Section 2 in Barigozzi, Brownlees and Lugosi (2018).
- For my portfolio application idea, see Moreira and Muir (2017) for volatility managed portfolios article in JoF. Portfolio selection with higher moments (Jondeau and Rockinger 2006)
- Write s in front of every standardized distribution. For example in the proof for the inverse FRiesz2 if you dont make it explicitly clear that you are working with non-standardized distributions it is maybe confusing.
- For the pdf, whenever $\mathbf{\Omega}$ is in the arguments it is the non-standardized version.
- Show that $\text{dg}(\mathbf{m})^{-1/2}i\mathcal{R}\text{dg}(\mathbf{m})^{-1/2}$ converges to a constant matrix. Same for cR , which is easier. Maybe if inverse matrix converges to some matrix it holds that matrix converges to inverse(some matrix)?
- Rigorously prove convergences in tikz picture.
- Should I name the dof for the inverse (t-)Riesz(Wishart) ν to stay consistent with the stochastic representation notation?
- Should I explicitly name all distributions "standardized" ...?
- Im forecasting Experiment die Zeitvariation der Parameter plotten.
- Zeitvariation in forecasting performance?
- Note to self: The relation e.g. $\mathbf{R} \sim \mathcal{R}^I(\mathbf{\Omega}, \boldsymbol{\theta}) \Rightarrow \mathbf{R}^{-1} \sim i\mathcal{R}^I(\mathbf{\Omega}^{-1}, \boldsymbol{\theta})$ for the Riezs-named only holds for the non-standardized versions.
- standardized, inverse klein schreiben.
- Add $\mathbf{\Omega}$ expression to "The expected value $\mathbb{E}[\mathbf{R}]$ obtains as ..."
- Name subscripts for pdfs p either everywhere or nowhere.

- Name it distribution of type ... or type-distribuiotn or distribution roman numeral, but not all three versions!
- “generalized power function” everywhere
- “ $p \times p$ ” matrix everywhere
- Put all “commented out” stuff into a legacy document.
- In tidying up the code, switch ν and n for inverse type *II* distributions as well.
- Add the Gribisch and Hartkopf 2022 interpretation of “missing trades” and the Wishart and t-Wishart interpretations in one spot.
- Thank Anne Opschoor, André Lucas, Timo Dimitriadis, Christian Conrad, Kris Boudt, Nestor Parolya, Jacques Faraut, Stephan Laurent (SE), Greg (SE), Michael Rockinger, (Eric Jondeau). Internal Seminar, CFE, HKMetrics Seminar, QFFE Seminar.
- Look at multi-step ahead forecasts at specific times, plotting them in terms of logdet, for several interesting distribution comparisons.
- Look at the behavior of \mathbf{Z} .
- Same order of distributions in all tables and figures.
- Update fig:StaticFitFRieszvsitRiesz.
- Add the GARCH special cases.
- logdet expectations.
- Make dfs time-varying.

Ideen (Maybe deprecated)

- Unsere 1-min Daten können benutzt werden, um eine tatsächliche Umschichtung des Portfolios zu simulieren, wobei man annehmen könnte direkt am nächsten Tag in den ersten 15 min die Umschichtung durchzunehmen.

- You cannot ground this paper in the multivariate semimartingale process, since theorem ?? below needs equal integrated covariance matrices over the high-frequency time window. That these are equal is a strong assumption, rejected by the data. You can of course start at the distributional assumption of \mathbf{r} and go from there, justifying that HF-returns keeps same covmat over the day. But this might also not convince. So you should focus on the t-wishart and its generalizations and its better fit and easy handabliity to covariance matrices.
- Díaz-García hat vermutet, dass die Riesz Verteilung aus der Summer äußerer Produkte von unabhängigen Zufallsvektoren entstpringt (siehe conclusion in Díaz-García 2013), konnte das aber nicht beweisen und hat stattdessen eine andere komplizierte Matrix-variate Verteilung gefunden für \mathbf{X} , sodass $\mathbf{X}\mathbf{X}'$ Riesz-verteilt ist (siehe Díaz-García 2016).
- Open research, show that the presented distributions do not fit some empirical patterns (fraction negative covariances, stylized fact that mainly pos covs and in crisis even more pos covs). Don't do this. Just before publishing this paper start your research in this direction.
- Djalil Chafaï schreiben um pd dist zu finden mit mehr Gewicht auf positiven Kovarianzen.
- invert color in fit table
- Relevance: What Jondeau said.
- ∇ is for GRADIENT! What you have is (total) derivative. https://en.wikipedia.org/wiki/Gradient#Gradient_and_the_derivative_or_differential
- Bei den Momenten und so noch die Bedingungen (bspw. $\nu > 1$) dabei schreiben.
- Der Kronecker Trick $\mathbf{G}\mathbf{G}^+(\mathbf{A} \otimes \mathbf{A}) = (\mathbf{A} \otimes \mathbf{A})\mathbf{G}\mathbf{G}^+$ funktioniert nur für das "Kronecker Quadrat" von \mathbf{A} , nicht für generelle Matrizen im Kronecker Produkt! Korrigiere das!
- Change $\dot{C}^{-\top}$ to something like U . Dann $\Omega = \mathbf{C}\mathbf{Y}\mathbf{C}^{\top}$ definieren und überall wo möglich reinschreiben.

- möglicherweise kommt man doch noch an die Kovarianzstruktur von inverse Riesz, wenn man die standardisierte für die Herleitung nimmt.
- Fit-Table: Only do one order, since the fit ranking is the same across orders and the fit itself doesn't improve substantially with orders. Maybe do the HAR specification of Anne.
- Forecasting Plot. Same as for Fit-Table. Ranking doesn't change across steps ahead and it flattens anyways, only report 1-step and maybe 10-step then you have one more dof for the plots.
- You NEED an economic application, why this is important, ideally one which even prefers your t-based distributions to the F-based ones. Turnover stuff maybe?
- Update this document with tables and figures from both Internal seminar and CFE presentations.
- Build a model with mixture distribution between itRiesz and FRiesz, where weight is determined by $\det(\mathbf{R}_{t-1})^{-50}$, $(\sum \mathbf{R}_{t-1,ii})^{-50}$ and the relative amount of positive correlations.

7.3 Abbreviations

Throughout the paper we exclusively consider real numbers. p is the cross-sectional dimension, i.e the number of assets, which we index by $i = 1, \dots, p$. If not otherwise specified, matrices are $p \times p$ and vectors are $p \times 1$.

\mathbf{R} is a symmetric positive definite random matrix or a realization thereof.

$\mathbf{\Sigma}$ and $\mathbf{\Omega}$ are symmetric positive (semi-)definite matrices.

\mathbf{C} denotes the lower Cholesky factor of $\mathbf{\Sigma} = \mathbf{C}\mathbf{C}^\top$.

\mathbf{n} and $\boldsymbol{\nu}$ are column vectors.

\mathbf{W} , \mathbf{X} , \mathbf{Y} , \mathbf{Z} generic matrices of any dimension.

\otimes denotes the Kronecker product.

\odot denotes element-wise multiplication.

7.4 Special Functions

Definition 7.1. Let \mathbf{X} be a real $p \times p$ matrix and let $\mathbf{X}_{[i]}$ denote the square submatrix created by taking the first i rows and columns of \mathbf{X} . Then the generalized power function, denoted by $|\mathbf{X}|_{\mathbf{n}}$ is defined as

$$|\mathbf{X}|_{\mathbf{n}} = |\mathbf{X}_{[1]}|^{n_1 - n_2} |\mathbf{X}_{[2]}|^{n_2 - n_3} \dots |\mathbf{X}_{[p-1]}|^{n_{p-1} - n_p} |\mathbf{X}|^{n_p}. \quad (42)$$

Note: The determinant with subscript notation was introduced by Blasques et al. 2021 to make immediately visible the close relation to the determinant raised to the power n , as it is easily seen that for $n_1 = n_2 = \dots = n_p = n$ we have $|\mathbf{X}|_{\mathbf{n}} = |\mathbf{X}|^n$. They name $|\mathbf{X}|_{\mathbf{n}}$ power weighted determinant. It is also known as highest weight vector.

Definition 7.2. Let \mathbf{X} be a $p \times p$ matrix, then the function $\Phi(\mathbf{X})$ takes the lower-triangular part of a matrix and halves its diagonal,

$$\Phi_{ij}(\mathbf{X}) = \begin{cases} \mathbf{X}_{ij} & \text{for } i > j, \\ \frac{1}{2} \mathbf{X}_{ii} & \text{for } i = j \text{ and} \\ 0 & \text{for } i < j. \end{cases} \quad (43)$$

Lemma 7.1. Let $\Sigma = \mathbf{TDT}^\top$ be the unique decomposition into lower triangular square matrix with ones on the main diagonal, \mathbf{T} and diagonal matrix with positive entries on the diagonal \mathbf{D} . Then we can rewrite

$$|\Sigma|_{\mathbf{n}} = \prod_{i=1}^p \mathbf{D}_{ii}^{n_i} = \prod_{i=1}^p \mathbf{C}_{ii}^{2n_i}. \quad (44)$$

Proof. The equivalence between the two different representation is proofed in Maaß 1971, pp. 69-70. This proof is closely based on it. If

$$\Sigma = \mathbf{TDT}^\top = \mathbf{CC}^\top, \quad (45)$$

then

$$\Sigma_{[j]} = \mathbf{C}_{[j]} \mathbf{C}_{[j]}^\top = \mathbf{T}_{[j]} \mathbf{D}_{[j]} \mathbf{T}_{[j]}^\top \quad (46)$$

. So

$$|\boldsymbol{\Sigma}_{[j]}| = \prod_{i=1}^j \mathbf{D}_{ii} \quad (47)$$

and thus

$$|\boldsymbol{\Sigma}_{[1]}| = \mathbf{D}_{11} \text{ and for } j > 1 \text{ we have } |\boldsymbol{\Sigma}_{[j]}|/|\boldsymbol{\Sigma}_{[j-1]}| = \mathbf{D}_{jj}. \quad (48)$$

Finally

$$\prod_{i=1}^p \mathbf{D}_{ii}^{s_i} = |\boldsymbol{\Sigma}_{[1]}|^{s_1} \prod_{i=2}^p (|\boldsymbol{\Sigma}_{[i]}|/|\boldsymbol{\Sigma}_{[i-1]}|)^{s_i} = |\boldsymbol{\Sigma}_{[1]}|^{s_1-s_2} |\boldsymbol{\Sigma}_{[2]}|^{s_2-s_3} \dots |\boldsymbol{\Sigma}_{[p]}|^{s_p}. \quad (49)$$

□

Lemma 7.2.

$$\left| \mathbf{C} \text{dg}(\mathbf{n}) \mathbf{C}^\top \right|_{\boldsymbol{\nu}} = \prod_{i=1}^p n_i^{\nu_i} |\boldsymbol{\Sigma}|_{\boldsymbol{\nu}}. \quad (50)$$

Proof.

$$\left| \mathbf{C} \text{dg}(\mathbf{n}) \mathbf{C}^\top \right|_{\boldsymbol{\nu}} = \prod_{i=1}^p (\mathbf{C}_{ii} \sqrt{n_i})^{2\nu_i} \quad (51)$$

$$= \prod_{i=1}^p \mathbf{C}_{ii}^{2\nu_i} \prod_{i=1}^p n_i^{\nu_i} \quad (52)$$

$$= \prod_{i=1}^p n_i^{\nu_i} \left| \mathbf{C} \mathbf{C}^\top \right|_{\boldsymbol{\nu}}. \quad (53)$$

□

Lemma 7.3. For \mathbf{n} with $n_i > i - 1$ we have,

$$\int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}|^{\frac{\mathbf{n}-p-1}{2}} \text{etr} \left(-\frac{1}{2} \mathbf{B} \mathbf{A} \right) d\mathbf{A} = 2^{p\bar{n}/2} \Gamma_p \left(\frac{\mathbf{n}}{2} \right) |\mathbf{B}^{-1}|_{\frac{\mathbf{n}}{2}} \quad (54)$$

and for $n_i < i - p$ we have,

$$\int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}^{-1}|_{\frac{\mathbf{n}+p+1}{2}} \operatorname{etr} \left(-\frac{1}{2} \mathbf{B} \mathbf{A} \right) d\mathbf{A} = \frac{1}{2^{p\bar{n}/2}} \Gamma_p \left(-\frac{\overleftarrow{\mathbf{n}}}{2} \right) |\mathbf{B}|_{\frac{\mathbf{n}}{2}}. \quad (55)$$

Proof. The proofs can be found in Faraut and Korányi 1994 Chapter VII.²⁵ Throughout, according to their table on p. 97, for the cone of symmetric positive definite matrices we have the dimension $n = p(p+1)/2$, the rank $r = p$ and $d = 1$.²⁶ Furthermore, throughout their book they use the Euclidean measure on a Euclidean space, which translated into our notation is $dx = \prod_{i=1}^p a_{ii} 2^{p(p-1)/4} \prod_{i < j} a_{ij} = 2^{p(p-1)/4} d\mathbf{A}$. Their use of the Euclidean measure leads to a slightly different multivariate gamma function. In particular from their Theorem VII.1.1.

$$\Gamma_{\Omega}(\mathbf{n}) = 2^{p(p-1)/4} \Gamma_p(\mathbf{n}), \quad (56)$$

with $\Gamma_p(\mathbf{n})$ as in (35.3.5) of the NIST Digital Library of Mathematical Functions.

Their Proposition VII.1.2., with $x = \mathbf{A}$, $y = \frac{1}{2} \mathbf{B}$ and $\mathbf{s} = \frac{\mathbf{n}}{2}$ translates to

$$\int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}|_{\frac{\mathbf{n}-p-1}{2}} \operatorname{etr} \left(-\frac{1}{2} \mathbf{B} \mathbf{A} \right) 2^{p(p-1)/4} d\mathbf{A} = 2^{p(p-1)/4} \Gamma_p \left(\frac{\mathbf{n}}{2} \right) |2\mathbf{B}^{-1}|_{\frac{\mathbf{n}}{2}} \quad (57)$$

$$= 2^{p(p-1)/4} \Gamma_p \left(\frac{\mathbf{n}}{2} \right) 2^{p\bar{n}/2} |\mathbf{B}^{-1}|_{\frac{\mathbf{n}}{2}}. \quad (58)$$

Their last equation on page 129 together with Proposition VII.1.5 (ii) and $x = \mathbf{A}$, $y = \frac{1}{2} \mathbf{B}$ and $\mathbf{s} = \frac{\mathbf{n}}{2}$ translates to

$$\int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}^{-1}|_{\frac{\mathbf{n}+p+1}{2}} \operatorname{etr} \left(-\frac{1}{2} \mathbf{B} \mathbf{A} \right) 2^{p(p-1)/4} d\mathbf{A} = 2^{p(p-1)/4} \Gamma_p \left(-\frac{\overleftarrow{\mathbf{n}}}{2} \right) \left| \frac{1}{2} \mathbf{B} \right|_{\frac{\mathbf{n}}{2}} \quad (59)$$

$$= 2^{p(p-1)/4} \Gamma_p \left(-\frac{\overleftarrow{\mathbf{n}}}{2} \right) \frac{1}{2^{p\bar{n}/2}} |\mathbf{B}|_{\frac{\mathbf{n}}{2}}. \quad (60)$$

□

Lemma 7.4. *Let the upper generalized multivariate gamma function be defined as in Blasques et al. 2021 and denote a vector with its elements in reverse order by a super-*

25. Further references are Díaz-García 2014, Maaß 1971 p. 76, Gupta and Nagar 2000, Theorem 1.4.7., which is based on Olkin, I. (1959). A class of integral identities with matrix argument. *Duke Mathematical Journal*, 26(2), 207–213. doi:10.1215/s0012-7094-59-02621-3, which in turn is based on the generalized Ingham formula in Bellman, R. (1956) (doi:10.1215/s0012-7094-56-02356-0).

26. For the notation see their Example 2 on p. 8 and p. 9.

script left arrow, e.g. $\overleftarrow{\mathbf{n}} = (n_p, n_{p-1}, \dots, n_1)^\top$, then

$$\Gamma_p(\overleftarrow{\mathbf{n}}) = \bar{\Gamma}_U(\mathbf{n}). \quad (61)$$

Proof. TODO. See Faraut and Korányi 1994. □

7.5 Matrix Relations

For matrices \mathbf{W} , \mathbf{X} , \mathbf{Y} and \mathbf{Z} with appropriate dimensions we have (Magnus and Neudecker 2019, p.12, p. 35)

$$\text{vec}(\mathbf{XYZ}) = (\mathbf{Z}^\top \otimes \mathbf{X}) \text{vec}(\mathbf{Y}), \quad (62)$$

$$\text{tr}(\mathbf{XYZ}) = \text{tr}(\mathbf{YZX}) = \text{tr}(\mathbf{ZXY}), \quad (63)$$

$$\text{tr}(\mathbf{X}^\top \mathbf{Y}) = \text{vec}(\mathbf{X})^\top \text{vec}(\mathbf{Y}) \text{ and} \quad (64)$$

$$\text{tr}(\mathbf{WXYZ}) = \text{vec}(\mathbf{W})^\top \text{vec}(\mathbf{XYZ}) = \text{vec}(\mathbf{W})^\top (\mathbf{X} \otimes \mathbf{Z}) \text{vec}(\mathbf{Y}), \quad (65)$$

where for the last equality we used (64) and (62).

7.5.1 Duplication, Elimination and Commutation Matrices

As a reference see Lütkepohl 2005, A.12.2. \mathbf{G}_p denotes the *duplication matrix* defined by

$$\text{vec}(\mathbf{X}) = \mathbf{G}_p \text{vech}(\mathbf{X}), \quad (66)$$

where \mathbf{X} is an arbitrary **symmetric** $p \times p$ matrix.

For symmetric \mathbf{X} the *duplication matrix* \mathbf{G} is unique, however the so called *elimination matrix*, which converts $\text{vec}(\mathbf{X})$ to $\text{vech}(\mathbf{X})$ is not unique (since for every lower-diagonal element of \mathbf{X} we can take a fraction c of the corresponding upper- and a fraction $1 - c$ of the lower-diagonal element of \mathbf{X}). One possible choice is the Moore-Penrose inverse of \mathbf{G}_p ,

$$\mathbf{G}_p^+ = (\mathbf{G}_p^\top \mathbf{G}_p)^{-1} \mathbf{G}_p^\top, \quad (67)$$

for which obviously

$$\mathbf{G}_p^+ \text{vec}(\mathbf{X}) = \mathbf{G}_p^+ \mathbf{G}_p \text{vech}(\mathbf{X}) = \text{vech}(\mathbf{X}). \quad (68)$$

Another possible choice is the canonical elimination matrix \mathbf{F}_p which sets the aforementioned fraction $c = 0$.

For **lower-triangular** $p \times p$ matrix \mathbf{Y} Magnus and Neudecker 1980 note (Lemma 3.3 (i)) the unique *elimination* and *duplication matrices* are given by

$$\text{vec}(\mathbf{Y}) = \mathbf{F}_p^\top \text{vech}(\mathbf{Y}) \quad (69)$$

and

$$\text{vech}(\mathbf{Y}) = \mathbf{F}_p \text{vec}(\mathbf{Y}). \quad (70)$$

\mathbf{K}_{pq} denotes the *commutation matrix* defined by

$$\text{vec}(\mathbf{Z}^\top) = \mathbf{K}_{pq} \text{vec}(\mathbf{Z}), \quad (71)$$

for arbitrary $p \times q$ matrix \mathbf{Z} . Note that the exact size and structure of \mathbf{G}_p , \mathbf{F}_p and \mathbf{K}_{pq} depends on the size of \mathbf{X} , but for better readability we choose to omit the size-indicating subscripts in the rest of this paper.

Magnus and Neudecker 2019 show (Theorem 3.12) that

$$(\mathbf{I} + \mathbf{K}) = 2\mathbf{G}\mathbf{G}^+. \quad (72)$$

Furthermore it holds that

$$\mathbf{G}\mathbf{G}^+ = \mathbf{G} \left(\mathbf{G}^\top \mathbf{G} \right)^{-1} \mathbf{G}^\top = \left(\mathbf{G} \left(\mathbf{G}^\top \mathbf{G} \right)^{-1} \mathbf{G}^\top \right)^\top = (\mathbf{G}\mathbf{G}^+)^\top \quad (73)$$

and

$$(\mathbf{G}^+)^\top \mathbf{G}^\top \text{vec}(\mathbf{X}) = \left(\left(\mathbf{G}^\top \mathbf{G} \right)^{-1} \mathbf{G}^\top \right)^\top \mathbf{G}^\top \mathbf{G} \text{vech}(\mathbf{X}) = \mathbf{G} \text{vech}(\mathbf{X}) = \text{vec}(\mathbf{X}). \quad (74)$$

For nonsingular matrix \mathbf{X} it holds that (see Lütkepohl 2005, p. 664 or Magnus and

Neudecker 2019, Theorem 3.13)

$$\left(\mathbf{G}^\top (\mathbf{X} \otimes \mathbf{X}) \mathbf{G}\right)^{-1} = \mathbf{G}^+ (\mathbf{X}^{-1} \otimes \mathbf{X}^{-1}) (\mathbf{G}^+)^{\top}. \quad (75)$$

Lemma 7.5. *For scalar α we have*

$$\left(\mathbf{G}^\top \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right) \mathbf{G}\right)^{-1} \quad (76)$$

$$= \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha}{1 + \alpha p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top\right) \mathbf{G}^+. \quad (77)$$

Proof.

$$\left(\mathbf{F} \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right)\right)^{-1} = \left(\mathbf{G}^+ \mathbf{G} \mathbf{F} \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right) \mathbf{G}\right)^{-1} \quad (78)$$

$$= \left(\mathbf{G}^+ \mathbf{G} \mathbf{F} \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right) \mathbf{G}\right)^{-1} \quad (79)$$

$$\text{Magnus and Neudecker 1980 Lemma 4.4 (i):} = \left(\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right) \mathbf{G}\right)^{-1} \quad (80)$$

$$= \left(\mathbf{G}^\top \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top\right) \mathbf{G}\right)^{-1} \mathbf{G}^\top \mathbf{G} \quad (81)$$

$$\text{Magnus and Neudecker 1980 Lemma 4.7 (iv):} = \mathbf{F} \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha}{1 + \alpha p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top\right) \mathbf{G} \quad (82)$$

$$\text{Magnus and Neudecker 1980 Lemma 4.4 (i):} = \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha}{1 + \alpha p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top\right) \mathbf{G}. \quad (83)$$

Then

$$(81) = (83) \tag{84}$$

$$\Leftrightarrow \tag{85}$$

$$\left(\mathbf{G}^\top \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} + \alpha \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \mathbf{G} \right)^{-1} \tag{86}$$

$$= \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} + \frac{\alpha}{1 + \alpha p} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}^+. \tag{87}$$

□

7.6 Matrix Derivatives

For properties of the **differential** “d” see Magnus and Neudecker 2019 pp. 163-169 and pp. 434-436. Some rules are

$$d\text{vec}(\mathbf{X}) = \text{vec}(d\mathbf{X}) \tag{88}$$

$$d\text{vec}(\mathbf{X}) = \mathbf{G} \text{vech}(d\mathbf{X}) \tag{89}$$

$$d\text{vech}(\mathbf{X}) = \mathbf{G}^+ \text{vec}(d\mathbf{X}) \tag{90}$$

$$d\mathbf{X}^\top = (d\mathbf{X})^\top \tag{91}$$

$$d\text{tr}(\mathbf{X}) = \text{tr}(d\mathbf{X}) \tag{92}$$

$$d \log |\mathbf{X}| = \text{tr}(\mathbf{X}^{-1} d\mathbf{X}) \tag{93}$$

$$d\mathbf{X}^{-1} = -\mathbf{X}^{-1} d\mathbf{X} \mathbf{X}^{-1} \tag{94}$$

$$d(\mathbf{X} \mathbf{X}^\top) = d\mathbf{X} \mathbf{X}^\top + \mathbf{X} d\mathbf{X}^\top \tag{95}$$

To convert differentials to derivatives see Tables 9.2 and 10.1 in Magnus and Neudecker 2019.

There is a difference between gradient and derivative of a scalar valued function that takes multiple input variables. They are transposes of each other, where the gradient is a column vector. See p. 87 Magnus and Neudecker 1999.

For the definition of a matrix derivative we follow Magnus 2010. For an $m \times p$ matrix function $\mathbf{F} = (f_{st})$ of an $n \times q$ matrix of variables $\mathbf{X} = (x_{ij})$, they define the α -derivative

as the $mp \times nq$ matrix

$$\frac{\partial \text{vec}(\mathbf{F}(\mathbf{X}))}{\partial \text{vec}(\mathbf{X})^\top}. \quad (96)$$

Note that

$$\frac{\partial \text{vech}(\bullet)}{\partial \bullet} = \frac{\partial \mathbf{G}^+ \text{vec}(\bullet)}{\partial \bullet} = \mathbf{G}^+ \frac{\partial \text{vec}(\bullet)}{\partial \bullet} \quad (97)$$

and

$$\frac{\partial \text{vec}(\bullet)}{\partial \bullet} = \frac{\partial \mathbf{G} \text{vech}(\bullet)}{\partial \bullet} = \mathbf{G} \frac{\partial \text{vech}(\bullet)}{\partial \bullet}. \quad (98)$$

Lemma 7.6. (*Magnus and Neudecker 1980, Lemma 3.8*). *Let \mathbf{X} be a $p \times p$ matrix of variables. Then*

$$\frac{\partial \text{vec}(\mathbf{X})}{\partial \text{vech}(\mathbf{X})^\top} = \begin{cases} \mathbf{F}^\top, & \text{for lower triangular } \mathbf{X}, \\ \mathbf{G}, & \text{for symmetric } \mathbf{X}, \end{cases} \quad (99)$$

Proof. We include a proof for completeness.

$$\text{vec}(d\mathbf{X}) = d\text{vec}(\mathbf{X}) = \begin{cases} d\mathbf{G} \text{vech}(\mathbf{X}) = \mathbf{G} d\text{vech}(\mathbf{X}), & \text{for lower triangular } \mathbf{X}, \\ d\mathbf{F}^\top \text{vech}(\mathbf{X}) = \mathbf{F}^\top d\text{vech}(\mathbf{X}), & \text{for symmetric } \mathbf{X}, \end{cases} \quad (100)$$

using (66) and (69). □

Lemma 7.7. (*Harville 1997, p. 371*). *Let \mathbf{X} be a non-singular symmetric matrix of variables. Then*

$$\frac{\partial \text{vech}(\mathbf{X}^{-1})}{\partial \text{vech}(\mathbf{X})^\top} = -\mathbf{G}^+ (\mathbf{X}^{-1} \otimes \mathbf{X}^{-1}) \mathbf{G}. \quad (101)$$

Proof. We include a proof for completeness.

$$\text{dvech}(\mathbf{X}^{-1}) = \text{d}\mathbf{G}^+ \text{vec}(\mathbf{X}^{-1}) \quad (102)$$

$$= -\mathbf{G}^+ \text{vec}(\mathbf{X}^{-1} \text{d}\mathbf{X}\mathbf{X}^{-1}) \quad (103)$$

$$= -\mathbf{G}^+ (\mathbf{X}^{-1} \otimes \mathbf{X}^{-1}) \text{dvec}(\mathbf{X}) \quad (104)$$

$$= -\mathbf{G}^+ (\mathbf{X}^{-1} \otimes \mathbf{X}^{-1}) \mathbf{G} \text{dvech}(\mathbf{X}), \quad (105)$$

using (68), (62) and (66). \square

7.6.1 Derivative - Trace

Lemma 7.8. *Let Σ be a non-singular symmetric $p \times p$ matrix of variables, \mathbf{C} its lower Cholesky factor and \mathbf{X} and \mathbf{Y} be $p \times p$ matrix of constants. Then*

$$\frac{\partial \text{tr}(\Sigma \mathbf{X})}{\partial \text{vech}(\Sigma)^\top} = \text{vec}(\mathbf{X})^\top \mathbf{G}, \quad (106)$$

$$\frac{\partial \text{tr}(\Sigma^{-1} \mathbf{X})}{\partial \text{vech}(\Sigma)^\top} = -\text{vec}(\Sigma^{-1} \mathbf{X} \Sigma^{-1})^\top \mathbf{G}, \quad (107)$$

$$\frac{\partial \text{tr}(\mathbf{C}^{-\top} \mathbf{X} \mathbf{C}^{-1} \mathbf{Y})}{\partial \text{vech}(\mathbf{C})^\top} = -2 \text{vec}(\mathbf{C}^{-\top} \mathbf{X} \mathbf{C}^{-1} \mathbf{Y} \mathbf{C}^{-\top})^\top \mathbf{F}^\top, \quad (108)$$

and

$$\frac{\partial^2 \text{tr}(\Sigma \mathbf{X})}{\partial \text{vech}(\Sigma) \partial \text{vech}(\Sigma)^\top} = \mathbf{0}. \quad (109)$$

Proof. We have

$$\text{dtr}(\Omega \mathbf{X}) = \text{tr}(\mathbf{X} \text{d}\Omega) \quad (110)$$

$$= \text{vec}(\mathbf{X})^\top \text{vec}(\text{d}\Omega) \quad (111)$$

$$= \text{vec}(\mathbf{X})^\top \mathbf{G} \text{dvech}(\Omega), \quad (112)$$

using (64) and (66),

$$\text{dtr}(\boldsymbol{\Sigma}^{-1}\mathbf{X}) = -\text{tr}(\boldsymbol{\Sigma}^{-1}\text{d}\boldsymbol{\Sigma}\boldsymbol{\Sigma}^{-1}\mathbf{X}) \quad (113)$$

$$= -\text{tr}(\boldsymbol{\Sigma}^{-1}\mathbf{X}\boldsymbol{\Sigma}^{-1}\text{d}\boldsymbol{\Sigma}) \quad (114)$$

$$= -\text{vec}(\boldsymbol{\Sigma}^{-1}\mathbf{X}\boldsymbol{\Sigma}^{-1})^\top \text{vec}(\text{d}\boldsymbol{\Sigma}) \quad (115)$$

$$= -\text{vec}(\boldsymbol{\Sigma}^{-1}\mathbf{X}\boldsymbol{\Sigma}^{-1})^\top \mathbf{G} \text{dvech}(\boldsymbol{\Sigma}), \quad (116)$$

using (63), (64) and (66),

$$\text{d}^2\text{tr}(\boldsymbol{\Sigma}\mathbf{X}) = \text{dtr}(\mathbf{X}\text{d}\boldsymbol{\Sigma}) = 0. \quad (117)$$

Furthermore,

$$\text{dtr}(\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1}\mathbf{Y}) = -\text{tr}((\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1})^{-\top}\mathbf{X}\mathbf{C}^{-1}\mathbf{Y} + \mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1}\mathbf{Y}) \quad (118)$$

$$= -\text{tr}(\text{d}\mathbf{C}^\top\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1}\mathbf{Y}\mathbf{C}^{-\top} + \mathbf{C}^{-1}\mathbf{Y}\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1}\text{d}\mathbf{C}) \quad (119)$$

$$= -2\text{tr}(\mathbf{C}^{-1}\mathbf{Y}\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1}\text{d}\mathbf{C}) \quad (120)$$

$$= -2\text{vec}(\mathbf{C}^{-1}\mathbf{Y}\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1})^\top \text{dvec}(\mathbf{C}) \quad (121)$$

$$= -2\text{vec}(\mathbf{C}^{-1}\mathbf{Y}\mathbf{C}^{-\top}\mathbf{X}\mathbf{C}^{-1})^\top \mathbf{F}^\top \text{dvech}(\mathbf{C}), \quad (122)$$

□

7.6.2 Derivative - CYC'

Lemma 7.9. *Let \mathbf{Y} be a diagonal matrix. Then*

$$\begin{aligned} \frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} &= \mathbf{G}\mathbf{G}^+(\mathbf{C}\mathbf{Y} \otimes \mathbf{I})\mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &= \mathbf{G}\mathbf{G}^+(\mathbf{C}\mathbf{Y} \otimes \mathbf{I})\mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I})\mathbf{F}^\top \right)^{-1}, \end{aligned} \quad (123)$$

$$\frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} = -\mathbf{G}\mathbf{G}^+(\mathbf{C}\mathbf{Y} \otimes \mathbf{I})\mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I})\mathbf{F}^\top \right)^{-1} \mathbf{G}^+ (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) \mathbf{G} \quad (124)$$

$$= -\mathbf{G}\mathbf{G}^+(\mathbf{C}\mathbf{Y} \otimes \mathbf{I})\mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1}, \quad (125)$$

$$\frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} = \mathbf{G} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) \mathbf{G} \quad (126)$$

$$= \mathbf{G} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \quad (127)$$

and

$$\frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = -\mathbf{G} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \quad (128)$$

$$= -\mathbf{G} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1}. \quad (129)$$

27

Proof. We have

$$\text{dvec}(\mathbf{C} \mathbf{Y} \mathbf{C}^\top) = \text{vec}(\text{d} \mathbf{C} \mathbf{Y} \mathbf{C}^\top) + \text{vec}(\mathbf{C} \mathbf{Y} \text{d} \mathbf{C}^\top) \quad (130)$$

$$= (\mathbf{I} + \mathbf{K}_{pp}) \text{vec}(\text{d} \mathbf{C} \mathbf{Y} \mathbf{C}^\top) \quad (131)$$

$$= (\mathbf{I} + \mathbf{K}_{pp}) (\mathbf{C} \mathbf{Y} \otimes \mathbf{I}) \text{vec}(\text{d} \mathbf{C}) \quad (132)$$

$$= 2 \mathbf{G} \mathbf{G}^+ (\mathbf{C} \mathbf{Y} \otimes \mathbf{I}) \mathbf{F}^\top \text{dvech}(\mathbf{C}), \quad (133)$$

$$\text{dvec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1}) = \text{vec}(\text{d} \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1}) + \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \text{d} \mathbf{C}^{-1}) \quad (134)$$

$$= -\mathbf{K}_{pp} \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \text{d} \mathbf{C} \mathbf{C}^{-1}) - \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \text{d} \mathbf{C} \mathbf{C}^{-1}) \quad (135)$$

$$= -(\mathbf{I} + \mathbf{K}_{pp}) \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \text{d} \mathbf{C} \mathbf{C}^{-1}) \quad (136)$$

$$= -(\mathbf{I} + \mathbf{K}_{pp}) \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \text{vec}(\text{d} \mathbf{C}) \quad (137)$$

$$= -2 \mathbf{G} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1} \right) \mathbf{F}^\top \text{dvech}(\mathbf{C}), \quad (138)$$

27. Note that in cases where two expressions are given those have been numerically checked to be the same. The longer versions make immediately obvious the nesting of the case where $\mathbf{Y} = c\mathbf{I}$. Magnus and Neudecker 1980 might offer tools for algebraic derivation of the equalities.

where we used (71), (62) and (72), such that

$$\frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} = 2\mathbf{G}\mathbf{G}^+(\mathbf{C}\mathbf{Y} \otimes \mathbf{I})\mathbf{F}^\top \quad (139)$$

and

$$\frac{\partial \text{vec}(\mathbf{C}^{-\top}\mathbf{Y}\mathbf{C}^{-1})}{\partial \text{vech}(\mathbf{C})^\top} = -2\mathbf{G}\mathbf{G}^+(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top}\mathbf{Y}\mathbf{C}^{-1})\mathbf{F}^\top. \quad (140)$$

Furthermore, according to Lemma 1 in Lütkepohl 1989 we have

$$\frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\mathbf{\Sigma})^\top} = \frac{1}{2} \left(\mathbf{G}^+(\mathbf{C} \otimes \mathbf{I})\mathbf{F}^\top \right)^{-1}, \quad (141)$$

for which we include the following proof for completeness,

$$\text{dvech}(\mathbf{\Sigma}) = \mathbf{G}^+ \text{dvec}(\mathbf{C}\mathbf{C}^\top) \quad (142)$$

$$= \mathbf{G}^+ \text{vec}(\text{d}\mathbf{C}\mathbf{C}^\top) + \mathbf{G}^+ \text{vec}(\mathbf{C}\text{d}\mathbf{C}^\top) \quad (143)$$

$$= \mathbf{G}^+(\mathbf{I} + \mathbf{K}_{pp}) \text{vec}(\text{d}\mathbf{C}\mathbf{C}^\top) \quad (144)$$

$$= \mathbf{G}^+\mathbf{G}\mathbf{G}^+ \text{vec}(\text{d}\mathbf{C}\mathbf{C}^\top) \quad (145)$$

$$= 2\mathbf{G}^+(\mathbf{C} \otimes \mathbf{I}) \text{vec}(\text{d}\mathbf{C}) \quad (146)$$

$$= 2\mathbf{G}^+(\mathbf{C} \otimes \mathbf{I})\mathbf{F}^\top \text{dvech}(\mathbf{C}). \quad (147)$$

Finally,

$$\text{dvech}(\mathbf{\Sigma}^{-1}) = \mathbf{G}^+ \text{dvec}(\mathbf{C}^{-\top}\mathbf{C}^{-1}) \quad (148)$$

$$= -\mathbf{G}^+ \text{vec}([\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1}]^\top \mathbf{C}^\top) - \mathbf{G}^+ \text{vec}(\mathbf{C}^{-\top}\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1}) \quad (149)$$

$$= -\mathbf{G}^+(\mathbf{I} + \mathbf{K}_{pp}) \text{vec}(\mathbf{C}^{-\top}\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1}) \quad (150)$$

$$= -\mathbf{G}^+\mathbf{G}\mathbf{G}^+ \text{vec}(\mathbf{C}^{-\top}\mathbf{C}^{-1}\text{d}\mathbf{C}\mathbf{C}^{-1}) \quad (151)$$

$$= -2\mathbf{G}^+(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top}\mathbf{C}^{-1}) \text{vec}(\text{d}\mathbf{C}) \quad (152)$$

$$= -2\mathbf{G}^+(\mathbf{C}^{-\top} \otimes \mathbf{\Sigma}^{-1})\mathbf{F}^\top \text{dvech}(\mathbf{C}). \quad (153)$$

such that

$$\frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} = -\frac{1}{2} \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1}. \quad (154)$$

Then the lemma follows by applying the chain rule,

$$\frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} \frac{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (155)$$

$$= \frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top}, \quad (156)$$

$$\frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} = \frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \frac{\partial \text{vech}(\boldsymbol{\Sigma})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} \quad (157)$$

$$= \frac{\partial \text{vec}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top}, \quad (158)$$

$$\frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} = \frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \frac{\partial \text{vech}(\boldsymbol{\Sigma})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} \quad (159)$$

$$= \frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top}, \quad (160)$$

$$\frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})^\top} \frac{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (161)$$

$$= \frac{\partial \text{vec}(\mathbf{C}^{-\top} \mathbf{Y} \mathbf{C}^{-1})}{\partial \text{vech}(\mathbf{C})^\top} \frac{\partial \text{vech}(\mathbf{C})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top}. \quad (162)$$

□

7.6.3 Derivative - Lower Power Weighted Determinant

Lemma 7.10.

$$\frac{\partial \log |\boldsymbol{\Sigma}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \text{vec} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (163)$$

and

$$\begin{aligned} \frac{\partial \log |\boldsymbol{\Sigma}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Sigma}) \text{vech}(\boldsymbol{\Sigma})^{\top}} &= -\mathbf{G}^{\top} \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{F}^{\top} \left(\mathbf{G}^{\top} \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^{\top} \right)^{-1} \\ &\quad \times \mathbf{G}^{\top} \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G} \end{aligned} \quad (164)$$

$$= -\mathbf{G}^{\top} \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{F}^{\top} \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^{\top} \right)^{-1} \quad (165)$$

Proof. Decompose $\boldsymbol{\Sigma} = \mathbf{T} \mathbf{D} \mathbf{T}^{\top}$, where \mathbf{T} is a lower triangular matrix with diagonal elements being 1 and \mathbf{D} is a diagonal matrix with positive diagonal elements, such that $\mathbf{C} = \mathbf{T} \mathbf{D}^{\frac{1}{2}}$ is the lower Cholesky factor. Note that

$$\frac{\partial \sum_{i=1}^p n_i \log(\mathbf{D}_{ii})}{\partial \mathbf{D}} = \begin{bmatrix} \frac{\mathbf{n}_1}{\mathbf{D}_{11}} & & & \\ & \frac{\mathbf{n}_2}{\mathbf{D}_{22}} & & \\ & & \ddots & \\ & & & \frac{\mathbf{n}_p}{\mathbf{D}_{pp}} \end{bmatrix} = \mathbf{D}^{-\frac{1}{2}} \text{dg}(\mathbf{n}) \mathbf{D}^{-\frac{1}{2}}, \quad (166)$$

such that

$$\frac{\partial \sum_{i=1}^p n_i \log(\mathbf{D}_{ii})}{\partial \text{vec}(\mathbf{D})^{\top}} = \text{vec} \left(\mathbf{D}^{-\frac{1}{2}} \text{dg}(\mathbf{n}) \mathbf{D}^{-\frac{1}{2}} \right)^{\top} \quad (167)$$

and

$$\text{dvec}(\boldsymbol{\Sigma}) = \text{dvec}(\mathbf{T} \mathbf{D} \mathbf{T}^{\top}) = (\mathbf{T} \otimes \mathbf{T}) \text{dvec}(\mathbf{D}), \quad (168)$$

such that

$$\frac{\partial \text{vec}(\mathbf{D})}{\partial \text{vec}(\boldsymbol{\Sigma})^{\top}} = (\mathbf{T} \otimes \mathbf{T})^{-1}. \quad (169)$$

Then

$$\frac{\partial \log |\boldsymbol{\Sigma}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Sigma})^{\top}} = \frac{\partial \sum_{i=1}^p n_i \log(\mathbf{D}_{ii})}{\partial \text{vec}(\mathbf{D})^{\top}} \frac{\partial \text{vec}(\mathbf{D})}{\partial \text{vec}(\boldsymbol{\Sigma})^{\top}} \frac{\partial \text{vec}(\boldsymbol{\Sigma})}{\partial \text{vech}(\boldsymbol{\Sigma})^{\top}} \quad (170)$$

$$= \text{vec} \left(\mathbf{D}^{-\frac{1}{2}} \text{dg}(\mathbf{n}) \mathbf{D}^{-\frac{1}{2}} \right)^{\top} (\mathbf{T} \otimes \mathbf{T})^{-1} \mathbf{G} \quad (171)$$

$$= \text{vec} \left(\mathbf{D}^{-\frac{1}{2}} \text{dg}(\mathbf{n}) \mathbf{D}^{-\frac{1}{2}} \right)^{\top} (\mathbf{T}^{-\top} \otimes \mathbf{T}^{-\top})^{\top} \mathbf{G} \quad (172)$$

$$= \text{vec} \left(\mathbf{T}^{-\top} \mathbf{D}^{-\frac{1}{2}} \text{dg}(\mathbf{n}) \mathbf{D}^{-\frac{1}{2}} \mathbf{T}^{-1} \right)^{\top} \mathbf{G} \quad (173)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right)^{\top} \mathbf{G}, \quad (174)$$

where we used (62).

Now application of Lemma (7.9) and using Theorem 3.13 (c) of Magnus and Neudecker 2019 on

$$\frac{\partial \log |\boldsymbol{\Sigma}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Sigma}) \text{vech}(\boldsymbol{\Sigma})^{\top}} = \mathbf{G}^{\top} \frac{\partial \text{vec}(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^{\top}} \quad (175)$$

gives

$$\begin{aligned} \frac{\partial \log |\boldsymbol{\Sigma}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Sigma}) \text{vech}(\boldsymbol{\Sigma})^{\top}} &= -\mathbf{G}^{\top} \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{F}^{\top} \\ &\quad \times \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^{\top} \right)^{-1} \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G}, \end{aligned}$$

with

$$\begin{aligned}
& \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G} \\
&= \left(\mathbf{G}^\top \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top \mathbf{G} \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G} \\
&= \left(\mathbf{G}^\top \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G} \\
&= \left(\mathbf{G}^\top \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \left(\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} \right) \left(\mathbf{G}^+ \right)^\top \right)^{-1} \\
&= \left(\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} \right) \left(\mathbf{G}^+ \right)^\top \mathbf{G}^\top \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \\
&= \left(\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} \right) \left(\mathbf{G} \mathbf{G}^+ \right)^\top \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \\
&= \left(\mathbf{G}^+ \mathbf{G} \mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} \right) \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \\
&= \left(\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma} \right) \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \\
&= \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1}.
\end{aligned}$$

□

Lemma 7.11. *Let $\boldsymbol{\Omega} = \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top$. Then*

$$\left(\frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \frac{\partial \log |\boldsymbol{\Omega}|_{\mathbf{n}}}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (176)$$

$$= \left(-\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y}^{-1} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1} \right)^\top \quad (177)$$

$$\times \mathbf{G}^\top \left(\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}_\Omega^{-\top} \otimes \boldsymbol{\Omega}^{-1} \right) \mathbf{F}^\top \right)^{-1} \quad (178)$$

$$\times \left(-\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y}^{-1} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1} \right) \quad (179)$$

$$= \left(-\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y}^{-1} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1} \right)^\top \quad (180)$$

$$\times \mathbf{G}^\top \left(\mathbf{C} \text{dg}(\mathbf{n})^{1/2} \otimes \mathbf{I} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}_\Omega^{-\top} \otimes \boldsymbol{\Omega}^{-1} \right) \mathbf{F}^\top \right)^{-1} \quad (181)$$

$$\times \left(-\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \mathbf{Y}^{-1} \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1} \right) \quad (182)$$

$$(183)$$

Another important related relation rewriting the derivative of the Cholesky factor

w.r.t. its “square matrix” (see equation (141)) derived in Murray 2016 based on (<https://mathoverflow.net/u/pav>) is given in the following Lemma.

Lemma 7.12.

$$\left(\frac{\partial \text{vech}(\mathbf{C}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C})^\top} \right)^{-1} \stackrel{\text{Lütkepohl 1989}}{=} \frac{1}{2} \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (184)$$

$$\stackrel{\text{Murray 2016}}{=} \mathbf{F} (\mathbf{I} \otimes \mathbf{C}) \mathbf{Z} (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (185)$$

$$\stackrel{\text{comment on mo}}{=} \frac{1}{2} \mathbf{F} (\mathbf{I} \otimes \mathbf{C}) (\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F}) (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (186)$$

$$\stackrel{\text{not proved yet}}{=} \frac{1}{2} \mathbf{F} (\mathbf{I} \otimes \mathbf{C}) (\mathbf{G}\mathbf{F})^\top (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G}, \quad (187)$$

where $\mathbf{Z} = \frac{1}{2}(\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F})$ (see comments in [mathoverflow post](#)) is a diagonal matrix defined such that for any square matrix \mathbf{A} , $\mathbf{Z}\text{vec}(\mathbf{A}) = \text{vec}(\Phi(\mathbf{A}))$, where $\Phi(\mathbf{A}) = \text{tril}(\mathbf{A} - \frac{1}{2}\mathbf{I} \odot \mathbf{A})$ returns \mathbf{A} with its upper triangular part set to 0's and its diagonals halved.

The next important one is

Lemma 7.13.

$$\mathbf{F}^\top \mathbf{F} \text{vec}(\mathbf{A}) = \text{vec}(\text{tril}(\mathbf{A})) \quad \text{and} \quad (188)$$

$$\frac{1}{2}(\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F}) \text{vec}(\mathbf{A}) = \text{vec}(\Phi(\mathbf{A})), \quad (189)$$

Proof. The first one is obvious, since \mathbf{F} eliminates those elements from $\text{vec}(\mathbf{A})$ which are on \mathbf{A} 's upper triangular part and then \mathbf{F}^\top we know from equation (69) is the matrix which maps vech_Δ to vec .

The second one we know from the aforementioned comment on [mathoverflow](#). For symmetric \mathbf{A} it obviously reduces to $\frac{1}{2}(\mathbf{G}\mathbf{F})^\top \text{vec}(\mathbf{A})$. \square

Finally this helps us with rewriting the scores in a format that is quick to evaluate, since it avoids Kronecker product products or inversions. To see this, consider

Lemma 7.14. *Let \mathbf{X} be a matrix, \mathbf{Y} a diagonal matrix, \mathbf{C} a lower triangular, \mathbf{G} , \mathbf{G}^+ and \mathbf{F} the duplication, its Moore-Penrose inverse and the canonical elimination matrix,*

as defined above. Then

$$\text{vec}(\mathbf{X})^\top \mathbf{G} \frac{\partial \text{vech}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C}\mathbf{C}^\top)} = 2 \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril}(\mathbf{X}\mathbf{C})\mathbf{Y} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (190)$$

Proof.

$$\text{vec}(\mathbf{X})^\top \mathbf{G} \frac{\partial \text{vech}(\mathbf{C}\mathbf{Y}\mathbf{C}^\top)}{\partial \text{vech}(\mathbf{C}\mathbf{C}^\top)} \quad (191)$$

$$\stackrel{(123)}{=} \text{vec}(\mathbf{X})^\top \mathbf{G}\mathbf{G}^+ (\mathbf{C}\mathbf{Y} \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (192)$$

$$\stackrel{(74)}{=} \text{vec}(\mathbf{X})^\top (\mathbf{C}\mathbf{Y} \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (193)$$

$$= \text{vec}(\mathbf{X}\mathbf{C}\mathbf{Y})^\top \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (194)$$

$$= \text{vec}(\mathbf{X}\mathbf{C}\mathbf{Y})^\top \mathbf{F}^\top \mathbf{F} (\mathbf{I} \otimes \mathbf{C}) (\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F}) (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (195)$$

$$\stackrel{(188)}{=} \text{vec}(\text{tril}(\mathbf{X}\mathbf{C})\mathbf{Y})^\top (\mathbf{I} \otimes \mathbf{C}) (\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F}) (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (196)$$

$$= \text{vec} \left(\mathbf{C}^\top \text{tril}(\mathbf{X}\mathbf{C})\mathbf{Y} \right)^\top (\mathbf{G}\mathbf{F})^\top (\mathbf{G}\mathbf{F}) (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (197)$$

$$\stackrel{(189)}{=} 2 \text{vec} \left(\Phi \left(\mathbf{C}^\top \text{tril}(\mathbf{X}\mathbf{C})\mathbf{Y} \right) \right)^\top (\mathbf{C}^{-1} \otimes \mathbf{C}^{-1}) \mathbf{G} \quad (198)$$

$$= 2 \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril}(\mathbf{X}\mathbf{C})\mathbf{Y} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (199)$$

Note that

$$\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril}(\mathbf{C}^{-\top} \text{dg}(\mathbf{n})) \right) \mathbf{C}^{-1} = \mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{dg}(\mathbf{C}^{-\top}) \text{dg}(\mathbf{n}) \right) \mathbf{C}^{-1} \quad (200)$$

$$= \mathbf{C}^{-\top} \text{dg} \left(\mathbf{C}^\top \right) \text{dg}(\mathbf{C}^{-\top}) \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \quad (201)$$

$$= \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1}. \quad (202)$$

□

7.7 Distributions

In the distribution-specific subsections below we omit subscripts i for indication of the respective distribution. For all distributions, \mathbf{R} denotes the symmetric positive definite

random matrix and

$$\boldsymbol{\Sigma} = \mathbf{C}\mathbf{C}^\top := \mathbb{E}[\mathbf{R}] \quad (203)$$

denotes the respective expected value, where \mathbf{C} denotes the lower Cholesky factor of $\boldsymbol{\Sigma}$. As described in section 2.1 EXPLAIN RESTRICTIONS ON DOFS AND DISTRIBUTIONS SPECIFIC DEFINITION OF OMEGA HERE. For the non-inverse Riesz type I named distributions and for the inverse Riesz type II named distributions we have to pre- and post multiply the random elements of the stochastic representations with the lower Cholesky factor of $\boldsymbol{\Sigma}$, whereas for the non-inverse Riesz type II named and for the inverse Riesz type I named distributions one has to use the upper Cholesky factor. To stay consistent and since we want to work only with one type of Cholesky decomposition, we choose type I distributions for the non-inverted Riesz named and type II distributions for the inverted ones.

For application in the GAS framework it is instructive to standardize all distributions (rewrite the pdfs in terms of $\boldsymbol{\Sigma}$ rather than their usual parameter matrix $\boldsymbol{\Omega}$) and derive the scores, Fisher information matrices and covariance matrices of the *standardized distributions*.

In the following we note the stochastic representation, pdf and expected value of the non-standardized distributions, then derive their standardized pdfs, covariance matrices, scores and fisher information matrices. All distributions we consider in this paper are matrix-variate distributions which have exactly one real symmetric positive definite parameter matrix (which we always denote by $\boldsymbol{\Omega}$) and one or more real scalar degree of freedom parameter (stacked in the vector $\boldsymbol{\theta}$) and whos expected value $\boldsymbol{\Sigma}$ is also a symmetric positive definite matrix. We denote the score with respect to $\boldsymbol{\Sigma}$ as

$$\nabla = \left(\frac{\partial \log \mathcal{L}}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top, \quad (204)$$

the Fisher information matrix with respect to $\boldsymbol{\Sigma}$ as

$$\mathcal{I} = \mathbb{E} \left[\frac{\partial \log \mathcal{L}}{\partial \text{vech}(\boldsymbol{\Sigma})} \left(\frac{\partial \log \mathcal{L}}{\partial \text{vech}(\boldsymbol{\Sigma})} \right)^\top \right] = -\mathbb{E} \left[\frac{\partial^2 \log \mathcal{L}}{\partial \text{vech}(\boldsymbol{\Sigma}) \partial \text{vech}(\boldsymbol{\Sigma})^\top} \right], \quad (205)$$

and our two versions of the standardized score as

$$\mathbf{S} = \text{ivech}(\mathcal{I}^{-1}\nabla) \quad (206)$$

and

$$\dot{\mathbf{S}} = \text{ivech}(\mathbf{Cov}(\text{vech}(\mathbf{R}))\nabla). \quad (207)$$

Theorem 7.1. *Let p^I denote a type-I distribution and p^{II} denote the corresponding a type-II distribution. Then*

$$p^I(\boldsymbol{\Omega}, \boldsymbol{\theta}) = p^{II}(\overleftarrow{\boldsymbol{\Omega}}, \overleftarrow{\boldsymbol{\theta}}) \quad (208)$$

and

$$p^I(\boldsymbol{\Sigma}, \boldsymbol{\theta}) = p^{II}(\overleftarrow{\boldsymbol{\Sigma}}, \overleftarrow{\boldsymbol{\theta}}), \quad (209)$$

where,

$$\begin{aligned} \text{if } \boldsymbol{\theta} = \mathbf{n}, \text{ then } \overleftarrow{\boldsymbol{\theta}} &= \overleftarrow{\boldsymbol{\nu}}, \\ \text{if } \boldsymbol{\theta} = \boldsymbol{\nu}, \text{ then } \overleftarrow{\boldsymbol{\theta}} &= \overleftarrow{\mathbf{n}} \text{ and} \\ \text{if } \boldsymbol{\theta} = (\mathbf{n}^\top, \boldsymbol{\nu}^\top)^\top, \text{ then } \overleftarrow{\boldsymbol{\theta}} &= (\overleftarrow{\boldsymbol{\nu}^\top}, \overleftarrow{\mathbf{n}^\top})^\top. \end{aligned}$$

Theorem 7.2. *Let p_I^s denote a standardized type-I distribution and p_{II}^s denote the corresponding standardized type-II distribution. Then*

$$p^I(\boldsymbol{\Sigma}, \boldsymbol{\theta}) = p^{II}(\overleftarrow{\boldsymbol{\Sigma}}, \overleftarrow{\boldsymbol{\theta}}), \quad (210)$$

with $\overleftarrow{\boldsymbol{\theta}} = (\overleftarrow{\mathbf{n}}, [\overleftarrow{\boldsymbol{\nu}}])$.

$\Sigma = CC^T = C_n M_n^T C_n^T$
 $f_1^S(CC^T, u, v) = f_1^S(C_n M_n^T C_n^T, u, v) = f_2^S((C_n M_n^T C_n^T)' = \Omega', u, v) = f_2^S(V_{(C_n M_n^T C_n^T)} V_{(C_n M_n^T C_n^T)}^T, u, v)$
 $\Sigma' = V_{(C_n M_n^T C_n^T)} V_{(C_n M_n^T C_n^T)}^T$ *numerisch stimmt*
 Prove that $f_1^S(\Sigma, u, v) = f_2^S(\Sigma', u, v)$:
 1. prove that $f_1^S(\Omega, u, v) = f_2^S(\Omega, u, v)$
 2. use \bullet to show that you only need to prove
 3. prove \bullet

Proof. □

Theorem 7.3 (Expectation of $\mathbf{B}\mathbf{B}^T$). Let $(\mathbf{B}_{ij})_{1 \leq j \leq i \leq p}$ be independent with $\mathbf{B}_{ii} \sim \chi_{n_i - i + 1}^2$, $n_i \geq i - 1$, and $\mathbf{B}_{ij} \sim \mathcal{N}(0, 1)$, i.e.

$$\mathbf{B} = \begin{bmatrix} \sqrt{\chi_{n_1 - 1 + 1}^2} & 0 & \dots & 0 \\ \mathcal{N}(0, 1) & \ddots & 0 & \vdots \\ \vdots & \mathcal{N}(0, 1) & \ddots & 0 \\ \mathcal{N}(0, 1) & \dots & \mathcal{N}(0, 1) & \sqrt{\chi_{n_p - p + 1}^2} \end{bmatrix}. \quad (211)$$

Then

$$\mathbb{E}[\mathbf{B}\mathbf{B}^T] = \text{dg}(\mathbf{n}), \quad (212)$$

with $\mathbf{n} = (n_1, n_2, \dots, n_p)^T$.

Proof. We have

$$(\mathbf{B}\mathbf{B}^T)_{ij} = \sum_{k=1}^p \mathbf{B}_{ik} (\mathbf{B}^T)_{kj} = \sum_{k=1}^p \mathbf{B}_{ik} \mathbf{B}_{jk}. \quad (213)$$

For the off-diagonal elements, i.e. $i \neq j$, we have

$$\mathbb{E}[(\mathbf{B}\mathbf{B}^T)_{ij}] = \sum_{k=1}^p \mathbb{E}[\mathbf{B}_{ik} \mathbf{B}_{jk}] = \sum_{k=1}^p \mathbb{E}[\mathbf{B}_{ik}] \mathbb{E}[\mathbf{B}_{jk}] = 0, \quad (214)$$

where we have used independence of the elements in \mathbf{B} and the fact that at least one of the elements in each summand above is a mean zero normal random variable. For the diagonal elements, i.e. $i = j$, we have

$$\left(\mathbf{B}\mathbf{B}^\top\right)_{ii} = \sum_{k=1}^p \mathbf{B}_{ik}^2 = \sum_{k=1}^i \mathbf{B}_{ik}^2, \quad (215)$$

which is the sum of a $\chi_{n_i-i+1}^2$ and $(i-1)$ independent $\mathcal{N}(0, 1)^2$ random variables, which implies that

$$\sum_{k=1}^i \mathbf{B}_{ik}^2 \sim \chi_{n_i}^2 \quad (216)$$

with expectation n_i . Thus

$$\mathbb{E}\left[\left(\mathbf{B}\mathbf{B}^\top\right)_{ii}\right] = n_i. \quad (217)$$

□

Theorem 7.4 (Expectation of $\bar{\mathbf{B}}\bar{\mathbf{B}}^\top$). *Let $(\bar{\mathbf{B}}_{ij})_{1 \leq i \leq j \leq p}$ be independent with $\bar{\mathbf{B}}_{ii} \sim \chi_{\nu_i-p+i}^2$, $\nu_i \geq p-i$, and $\bar{\mathbf{B}}_{ij} \sim \mathcal{N}(0, 1)$, i.e.*

$$\bar{\mathbf{B}} = \begin{bmatrix} \sqrt{\chi_{\nu_1-p+1}^2} & \mathcal{N}(0, 1) & \dots & \mathcal{N}(0, 1) \\ 0 & \ddots & \mathcal{N}(0, 1) & \vdots \\ \vdots & 0 & \ddots & \mathcal{N}(0, 1) \\ 0 & \dots & 0 & \sqrt{\chi_{\nu_p-p+p}^2} \end{bmatrix}, \quad (218)$$

Then

$$\mathbb{E}\left[\left(\bar{\mathbf{B}}\bar{\mathbf{B}}^\top\right)^{-1}\right] = \text{dg}(\mathbf{m}) \quad (219)$$

where the entries of the vector $\mathbf{m} = (m_1, \dots, m_p)^\top$ are given by

$$m_i = \begin{cases} \frac{1}{n_i-p-1}, & \text{for } i = 1 \\ \frac{1}{n_i-p+i-2} \left(1 + \sum_{j=1}^{i-1} m_j\right) & \text{for } i > 1. \end{cases} \quad (220)$$

Proof. ToDo □

7.7.1 Riesz

Theorem 7.5. *Let*

$$\mathbf{R} = \mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \mathbf{B} \mathbf{B}^\top \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top, \quad (221)$$

then \mathbf{R} is said to follow a standardized Riesz distribution of type I denoted by $\mathbf{R} \sim \mathcal{R}^I(\boldsymbol{\Sigma}, \mathbf{n})$. The probability density function of \mathbf{R} is

$$p(\mathbf{R} | \boldsymbol{\Sigma}, \mathbf{n}) = \frac{\prod_{i=1}^p n_i^{n_i/2}}{2^{p\bar{\mathbf{n}}/2} \Gamma_p(\mathbf{n}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{n}) \mathbf{Z} \right). \quad (222)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma}, \quad (223)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \mathbf{R} \mathbf{C}^{-\top} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \right) \right) \mathbf{C}^{-1} \right) \quad (224)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = \frac{1}{2} \mathbf{G}^\top \mathbf{G} \left(\mathbf{F}(\mathbf{C}^\top \otimes \mathbf{I}) \mathbf{G} \right)^{-1} \mathbf{F} \left(\mathbf{C}^{-1} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{G}. \quad (225)$$

Proof. For the probability density function of $\mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \mathbf{B} \mathbf{B}^\top \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top$ see Blasques et al. 2021, theorem 4, with $\boldsymbol{\Sigma}_{\text{Blasques}} = \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top$, i.e. $\mathbf{C}_{\text{Blasques}} = \mathbf{C} \text{dg}(\mathbf{n})^{-1/2}$.²⁸

²⁸. See also Kessentini, Tounsi, and Zine 2020

Using Lemma (7.1) of this paper and Lemma 3 (v) of Blasques et al. 2021 we have

$$p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}) = \frac{1}{2^{p\bar{n}/2}\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} \left(\left| \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right|_{\frac{\mathbf{n}}{2}} \right)^{-1} \text{etr} \left(-\frac{1}{2} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \mathbf{R} \right) \quad (226)$$

$$= \frac{\prod_{i=1}^p n_i^{n_i/2}}{2^{p\bar{n}/2}} \frac{1}{\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} |\boldsymbol{\Sigma}|_{-\frac{\mathbf{n}}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \mathbf{R} \mathbf{C}^{-\top} \right) \quad (227)$$

$$= \frac{\prod_{i=1}^p n_i^{n_i/2}}{2^{p\bar{n}/2}} \frac{1}{\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{n}) \mathbf{Z} \right). \quad (228)$$

For the expected value simply apply theorem 7.3,

$$\mathbb{E} \left[\mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \mathbf{B} \mathbf{B}^\top \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top \right] = \mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \mathbb{E} \left[\mathbf{B} \mathbf{B}^\top \right] \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top \quad (229)$$

$$= \mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top = \boldsymbol{\Sigma}. \quad (230)$$

Now, define for better readability $\boldsymbol{\Omega} = \boldsymbol{\Sigma}_{Blasques}$. For the score w.r.t. $\boldsymbol{\Sigma}$ start from equation (226), such that

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (231)$$

$$= \left(\frac{\partial \log |\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}}{\partial \text{vech}(\boldsymbol{\Omega})^\top} - \frac{1}{2} \frac{\partial \text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \right) \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (232)$$

$$(7.8), (7.10) = \frac{1}{2} \text{vec} \left(-\mathbf{C} \boldsymbol{\Omega}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C} \boldsymbol{\Omega}^{-1} + \boldsymbol{\Omega}^{-1} \mathbf{R} \boldsymbol{\Omega}^{-1} \right)^\top \mathbf{G} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (233)$$

$$(199) = \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\boldsymbol{\Omega}^{-1} \mathbf{R} \boldsymbol{\Omega}^{-1} \mathbf{C} - \mathbf{C} \boldsymbol{\Omega}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C} \boldsymbol{\Omega}^{-1} \right) \text{dg}(\mathbf{n})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (234)$$

Now, using the definition of $\boldsymbol{\Omega}$ and $\mathbf{C} \boldsymbol{\Omega} = \mathbf{C} \text{dg}(\mathbf{n})^{-1/2}$ this reduces to

$$\text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\boldsymbol{\Omega}^{-1} \mathbf{R} \boldsymbol{\Omega}^{-1} \mathbf{C} - \mathbf{C} \boldsymbol{\Omega}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C} \boldsymbol{\Omega}^{-1} \right) \text{dg}(\mathbf{n})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (235)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \mathbf{R} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) - \mathbf{C}^{-\top} \text{dg}(\mathbf{n})^2 \right) \text{dg}(\mathbf{n})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (236)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \mathbf{R} \mathbf{C}^{-\top} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \right) \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (237)$$

For the Fisher information matrix with respect to Σ we first derive the Fisher information matrix with respect to Ω . Using Lemma ??,

$$\mathcal{I}_\Omega = - \left(\frac{\partial \text{vech}(\Omega^{-1})}{\partial \text{vech}(\Omega)^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\Sigma, \mathbf{n})}{\partial \text{vech}(\Omega^{-1}) \partial \text{vech}(\Omega^{-1})^\top} \right] \frac{\partial \text{vech}(\Omega^{-1})}{\partial \text{vech}(\Omega)^\top} \quad (238)$$

where the expectation, using Lemma 7.8 and Lemma 7.10, boils down to

$$\mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\Sigma, \mathbf{n})}{\partial \text{vech}(\Omega^{-1}) \partial \text{vech}(\Omega^{-1})^\top} \right] \quad (239)$$

$$= \mathbb{E} \left[\frac{\partial^2 \log |\Omega|_{-\frac{n}{2}}}{\partial \text{vech}(\Omega^{-1}) \partial \text{vech}(\Omega^{-1})^\top} - \frac{\partial^2 \text{tr}(\frac{\Omega^{-1} \mathbf{R}}{2})}{\partial \text{vech}(\Omega^{-1}) \partial \text{vech}(\Omega^{-1})^\top} \right] \quad (240)$$

$$= -\frac{1}{2} \mathbf{G}^\top (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^\top (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top (\Omega \otimes \Omega) \mathbf{G}. \quad (241)$$

Then, using Lemma (7.7), we have

$$\mathcal{I}_\Omega = \mathbf{G}^\top (\Omega^{-1} \otimes \Omega^{-1}) (\mathbf{G}^+)^\top \quad (242)$$

$$\times \frac{1}{2} \mathbf{G}^\top (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^\top (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top (\Omega \otimes \Omega) \mathbf{G} \quad (243)$$

$$\times \mathbf{G}^+ (\Omega^{-1} \otimes \Omega^{-1}) \mathbf{G} \quad (244)$$

$$= \frac{1}{2} \mathbf{G}^\top (\Omega^{-1} \otimes \Omega^{-1}) (\mathbf{G} \mathbf{G}^+)^\top (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (245)$$

$$= \frac{1}{2} \mathbf{G}^\top (\Omega^{-1} \otimes \Omega^{-1}) \mathbf{G} \mathbf{G}^+ (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (246)$$

$$= \frac{1}{2} \mathbf{G}^\top (\Omega^{-1} \otimes \Omega^{-1}) (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (247)$$

$$= \frac{1}{2} \mathbf{G}^\top \left(\mathbf{C}_\Omega^{-\top} \text{dg}(\mathbf{n}) \otimes \Omega^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1}. \quad (248)$$

Using again Lemma ??

$$\mathcal{I} = \left(\frac{\partial \text{vech}(\Omega)}{\partial \text{vech}(\Sigma)^\top} \right)^\top \mathcal{I}_\Omega \frac{\partial \text{vech}(\Omega)}{\partial \text{vech}(\Sigma)^\top}, \quad (249)$$

rewrite in terms of \mathbf{C} and Σ , on the right multiplication you can use equation (??) on the left hand side standard arguments to arrive at

$$\frac{1}{2} \mathbf{G}^\top \mathbf{G} \left(\mathbf{F} (\mathbf{C}^\top \otimes \mathbf{I}) \mathbf{G} \right)^{-1} \mathbf{F} \left(\mathbf{C}^{-1} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{G}. \quad (250)$$

Later on, for the derivation of the Fisher information matrix of the t-Riesz distribution we will need the covariance matrix of $\text{vech}(\mathbf{R})$, which can be derived as follows. First, see §2.1.2 of Kollo and Rosen 2005 for the characteristic function of a patterned (in our case symmetric) matrix variate distribution. Note there are two approaches here. Either we ignore symmetry and get the characteristic function of $\text{vec}(\mathbf{R})$ or we take it into account by getting the characteristic function of e.g. $\text{vech}(\mathbf{R})$. In consistency with the rest of this paper we take symmetry into account. Díaz-García 2013 and Gribisch and Hartkopf 2022 don't. Gupta and Nagar 2000 and Kollo and Rosen 2005 do. The characteristic function of $\text{vech}(\mathbf{A})$ where $\mathbf{A} = \mathbf{B}\mathbf{B}^\top$ is given by

$$\phi(\mathbf{Z}) = \mathbb{E} \left[e^{i \text{vech}(\mathbf{Z})^\top \text{vech}(\mathbf{A})} \right] \quad (251)$$

$$= \mathbb{E} \left[\text{etr} \left(i \frac{1}{2} (\mathbf{Z} + \mathbf{Z}) \mathbf{A} \right) \right] \text{ p. 244 Kollo and Rosen 2005} \quad (252)$$

$$= \frac{1}{2^{p\bar{n}/2} \Gamma_p(\mathbf{n}/2)} \int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}|^{\frac{\mathbf{n}-p-1}{2}} \text{etr} \left(i \frac{1}{2} (\mathbf{Z} + \mathbf{Z}) \mathbf{A} \right) \text{etr} \left(-\frac{1}{2} \mathbf{I} \mathbf{A} \right) \quad (253)$$

$$= \frac{1}{2^{p\bar{n}/2} \Gamma_p(\mathbf{n}/2)} \int_{\mathbf{A} > \mathbf{0}} |\mathbf{A}|^{\frac{\mathbf{n}-p-1}{2}} \text{etr} \left(-\frac{1}{2} (\mathbf{I} - i(\mathbf{Z} + \mathbf{Z})) \mathbf{A} \right) \quad (254)$$

$$= \frac{1}{2^{p\bar{n}/2} \Gamma_p(\mathbf{n}/2)} \Gamma_p(\mathbf{n}/2) \left| \frac{1}{2} (\mathbf{I} - i(\mathbf{Z} + \mathbf{Z}))^{-1} \right|_{\frac{\mathbf{n}}{2}} \quad (255)$$

$$= \frac{1}{2^{p\bar{n}/2}} 2^{p\bar{n}/2} \left| (\mathbf{I} - i(\mathbf{Z} + \mathbf{Z}))^{-1} \right|_{\frac{\mathbf{n}}{2}} \quad (256)$$

$$= \left| (\mathbf{I} - i(\mathbf{Z} + \mathbf{Z}))^{-1} \right|_{\frac{\mathbf{n}}{2}}, \quad (257)$$

where \mathbf{Z} is a diagonal matrix with elements $\text{dg}(\mathbf{Z})$ and where we used Lemma (7.3). See also Díaz-García 2013, Lemma 1.

Denote $\mathbf{\Xi} = \mathbf{I} - i(\mathbf{Z} + \mathbf{Z})$, then

$$\frac{\partial \text{vech}(\mathbf{\Xi})}{\partial \text{vech}(\mathbf{Z})^\top} = -i2 \left(\mathbf{G}^\top \mathbf{G} \right)^{-1} = -i2 \left(\mathbf{G}^\top \mathbf{G} \right)^{-\top} \quad (258)$$

Commented out is an alternative way using the characteristic function to derive the expectation.

Then

$$\frac{\partial^2 \phi(\mathbf{Z})}{\partial \text{vech}(\mathbf{Z}) \partial \text{vech}(\mathbf{Z})^\top} = i \frac{\partial}{\partial \text{vech}(\mathbf{Z})} \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)^\top \quad (259)$$

$$= i \frac{\partial \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}}}{\partial \text{vech}(\mathbf{Z})} \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)^\top + i \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \frac{\partial \text{vec} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)}{\partial \text{vech}(\mathbf{Z})} (\mathbf{G}^+)^\top \quad (260)$$

$$= i^2 \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right) \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)^\top \quad (261)$$

$$- i \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \left(\frac{\partial \text{vec} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)}{\partial \text{vech}(\boldsymbol{\Xi})^\top} \frac{\partial \text{vech}(\boldsymbol{\Xi})}{\partial \text{vech}(\mathbf{Z})^\top} \right)^\top (\mathbf{G}^+)^\top \quad (262)$$

$$= i^2 \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right) \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)^\top \quad (263)$$

$$+ i^2 2 \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \left(\mathbf{G} \mathbf{G}^+ \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \otimes \mathbf{I} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\dot{\mathbf{C}}_\xi^{-\top} \otimes \boldsymbol{\Xi} \right) \mathbf{F}^\top \right)^{-1} \left(\mathbf{G}^\top \mathbf{G} \right)^{-\top} \right)^\top \quad (264)$$

$$= i^2 \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right) \text{vech} \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \dot{\mathbf{C}}_\xi^\top \right)^\top \quad (265)$$

$$+ i^2 2 \left| \boldsymbol{\Xi}^{-1} \right|_{\frac{n}{2}} \left(\mathbf{G}^\top \mathbf{G} \right)^{-1} \left(\mathbf{G} \mathbf{G}^+ \left(\dot{\mathbf{C}}_\xi \text{dg}(\mathbf{n}) \otimes \mathbf{I} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\dot{\mathbf{C}}_\xi^{-\top} \otimes \boldsymbol{\Xi} \right) \mathbf{F}^\top \right)^{-1} \right)^\top \quad (266)$$

where $\dot{\mathbf{C}}_\xi$ is the lower Cholesky factor of $\boldsymbol{\Xi}^{-1}$, such that

$$\mathbb{E} \left[\text{vech}(\mathbf{A}) \text{vech}(\mathbf{A})^\top \right] = \frac{\partial^2 \phi(\mathbf{Z})}{i^2 \partial \text{vech}(\mathbf{Z}) \partial \text{vech}(\mathbf{Z})^\top} \Big|_{\mathbf{Z}=\mathbf{0}} \quad (267)$$

$$= \text{vech}(\text{dg}(\mathbf{n})) \text{vech}(\text{dg}(\mathbf{n}))^\top \quad (268)$$

$$+ 2 \left(\mathbf{G}^\top \mathbf{G} \right)^{-1} \left(\mathbf{G} \mathbf{G}^+ (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{I} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \right)^\top (\mathbf{G}^+)^\top \quad (269)$$

$$= \text{vech}(\text{dg}(\mathbf{n})) \text{vech}(\text{dg}(\mathbf{n}))^\top + 2 \mathbf{G}^+ \left((\text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{G} \mathbf{G}^+ \mathbf{F}^\top \left(\mathbf{G}^+ \mathbf{F}^\top \right)^{-1} \right)^\top (\mathbf{G}^+)^\top \quad (270)$$

$$= \text{vech}(\text{dg}(\mathbf{n})) \text{vech}(\text{dg}(\mathbf{n}))^\top + 2 \mathbf{G}^+ (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) (\mathbf{G}^+)^\top. \quad (271)$$

and consequently

$$\mathbf{Cov}(\text{vech}(\mathbf{A})) = 2\mathbf{G}^+ (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) (\mathbf{G}^+)^{\top}. \quad (272)$$

Finally

$$\mathbf{Cov}(\text{vech}(\mathbf{R})) = \mathbf{Cov}\left(\text{vech}\left(\mathbf{C}_{\Omega}\mathbf{A}\mathbf{C}_{\Omega}^{\top}\right)\right) \quad (273)$$

$$= \mathbf{G}^+ (\mathbf{C}_{\Omega} \otimes \mathbf{C}_{\Omega}) \mathbf{G} \mathbf{Cov}(\text{vech}(\mathbf{A})) (\mathbf{G}^+ (\mathbf{C}_{\Omega} \otimes \mathbf{C}_{\Omega}) \mathbf{G})^{\top} \quad (274)$$

$$= 2\mathbf{G}^+ (\mathbf{C}_{\Omega} \otimes \mathbf{C}_{\Omega}) \mathbf{G} \mathbf{G}^+ (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) (\mathbf{G}^+)^{\top} (\mathbf{G}^+ (\mathbf{C}_{\Omega} \otimes \mathbf{C}_{\Omega}) \mathbf{G})^{\top} \quad (275)$$

$$= 2\mathbf{G}^+ (\mathbf{C}_{\Omega} \otimes \mathbf{C}_{\Omega}) (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) (\mathbf{C}_{\Omega}^{\top} \otimes \mathbf{C}_{\Omega}^{\top}) (\mathbf{G}^+)^{\top} \quad (276)$$

$$= 2\mathbf{G}^+ \left(\boldsymbol{\Sigma} \otimes \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^{\top}\right) (\mathbf{G}^+)^{\top}. \quad (277)$$

Commented out is the proof that the scaling of the score by the inverse Fisherinfo yields standard GARCH dynamics in the standard GAS model using the Riesz distribution.

□

7.7.2 Wishart Distribution

Theorem 7.6. *Let*

$$\mathbf{R} = \frac{1}{n} \mathbf{C} \underline{\mathbf{B}} \underline{\mathbf{B}}^\top \mathbf{C}^\top, \quad (278)$$

then \mathbf{R} is said to follow a standardized Wishart distribution denoted by $\mathbf{R} \sim \mathcal{W}(\boldsymbol{\Sigma}, \mathbf{n})$.

The probability density function of \mathbf{R} is

$$p(\mathbf{R} | \boldsymbol{\Sigma}, \mathbf{n}) = \frac{n^{np/2}}{2^{np/2} \Gamma_p(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{\frac{n}{2}} \text{etr} \left(-\frac{1}{2} n \mathbf{Z} \right). \quad (279)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma}, \quad (280)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \frac{1}{2} \mathbf{G}^\top \text{vec} (n \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1}) \quad (281)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = \frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}. \quad (282)$$

Proof. Remember that the Wishart distribution is just a special case of the Riesz distribution, with all degree of freedom parameters being equal,

$$n_1, \dots, n_p = n. \quad (283)$$

Using this, the probability density function²⁹ is easily obtained from (222). The expected value remains the same as for the Riesz. For the score, start from (233), observe that for $n_1, \dots, n_p = n$, $\boldsymbol{\Sigma} = n \boldsymbol{\Omega}$ to arrive at

$$\frac{1}{2} \mathbf{G}^\top \text{vec} (-n^2 \boldsymbol{\Sigma}^{-1} + n^2 \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1}) \frac{1}{n} = \frac{1}{2} \mathbf{G}^\top \text{vec} (n \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1}). \quad (284)$$

²⁹. See also Muirhead 1982, Theorem 3.2.1.

For the Fisher information matrix start from (247) to arrive at

$$\mathcal{I}_\Omega = \frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (285)$$

$$= \frac{n}{2} \mathbf{G}^\top \mathbf{G} \mathbf{G}^+ (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (286)$$

$$= \frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \mathbf{G} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (287)$$

$$= \frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \mathbf{G}. \quad (288)$$

Then again using $\boldsymbol{\Sigma} = n\boldsymbol{\Omega}$ we have

$$\mathcal{I} = \left(\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathcal{I}_\Omega \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (289)$$

$$= \frac{n}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}. \quad (290)$$

Commented out here are the covariance structure and the proof that when scaling the score with the inverse Fisher info we arrive at a standard GARCH structure from the standard GAS dynamics.

□

7.7.3 Inverse Riesz

Theorem 7.7. *Let*

$$\mathbf{R} = \mathbf{C} \text{dg}(\mathbf{m}^{\text{Riesz}})^{-1/2} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{Riesz}})^{-1/2} \mathbf{C}^\top, \quad (291)$$

then \mathbf{R} is said to follow a standardized Riesz distribution of type II denoted by $\mathbf{R} \sim \mathcal{R}^{II}(\boldsymbol{\Sigma}, \boldsymbol{\nu})$, with $\mathbf{m}^{\text{Riesz}} = (m_1^{\text{Riesz}}, \dots, m_p^{\text{Riesz}})^\top$,

$$m_i^{\text{Riesz}} = \begin{cases} \frac{1}{\nu_i - p - 1}, & \text{for } i = 1 \\ \frac{1}{\nu_i - p + i - 2} \left(1 + \sum_{j=1}^{i-1} m_j^{\text{Riesz}}\right) & \text{for } i > 1. \end{cases} \quad (292)$$

The probability density function of \mathbf{R} is

$$p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu}) = \frac{\prod_{i=1}^p (m_i^{\text{Riesz}})^{-\nu_i/2}}{2^{p\bar{\nu}/2}} \frac{1}{\Gamma_p(\bar{\nu}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{m}^{\text{Riesz}})^{-1} \mathbf{Z}^{-1} \right). \quad (293)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} \quad (294)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = -\mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{\text{Riesz}})^{-1} - \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) \right) \right) \mathbf{C}^{-1} \right) \quad (295)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = - \left(\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (296)$$

with

$$\begin{aligned} & \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \\ &= -\frac{1}{2} \mathbf{G}^\top \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{\text{Riesz}})^{1/2} \otimes \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) \text{dg}(\mathbf{m}^{\text{Riesz}}) \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \text{dg}(\mathbf{m}^{\text{Riesz}})^{-1/2} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1}. \end{aligned} \quad (298)$$

and

$$\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \mathbf{G}^+ (\mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1}. \quad (299)$$

Proof. For the probability density function of $\mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1/2} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{r''})^{-1/2} \mathbf{C}^\top$ see Blasques et al. 2021. According to their, theorem 4 (ii) and definition 6 (ii), $\mathbf{U}^{-\top} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \mathbf{U}^{-1}$, where \mathbf{U} is the upper Cholesky factor of $\boldsymbol{\Sigma}_{Blasques}^{-1}$ and consequently $\mathbf{U}^{-\top} = \mathbf{C}_{Blasques}$, where $\mathbf{C}_{Blasques}$ is the lower Cholesky factor of $\boldsymbol{\Sigma}_{Blasques}$, follows an inverse Riesz distribution of type II. Now set $\boldsymbol{\Sigma}_{Blasques} = \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{C}^\top$ and use their theorem 7 to obtain

$$f(\mathbf{R}|\boldsymbol{\Omega}, \boldsymbol{\nu}) = \frac{1}{2^{p\bar{\nu}/2} \Gamma_p(\boldsymbol{\nu}/2)} U |\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{r''}) \mathbf{C}^{-1}|_{-\frac{\nu}{2}} U |\mathbf{R}^{-1}|_{\frac{\nu+p+1}{2}} \text{etr} \left(-\frac{1}{2} \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{C}^\top \mathbf{R}^{-1} \right) \quad (300)$$

$$= \frac{1}{2^{p\bar{\nu}/2} \Gamma_p(\bar{\boldsymbol{\nu}}/2)} |\mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{C}^\top|_{\frac{\nu}{2}} |\mathbf{R}|_{-\frac{\nu+p+1}{2}} \text{etr} \left(-\frac{1}{2} \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{C}^\top \mathbf{R}^{-1} \right) \quad (301)$$

$$= \frac{\prod_{i=1}^p (m_i^{r''})^{-\nu_i/2}}{2^{p\bar{\nu}/2} \Gamma_p(\bar{\boldsymbol{\nu}}/2)} |\boldsymbol{\Sigma}|_{\frac{\nu}{2}} |\mathbf{R}|_{-\frac{\nu+p+1}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{Z}^{-1} \right) \quad (302)$$

$$= \frac{\prod_{i=1}^p (m_i^{r''})^{-\nu_i/2}}{2^{p\bar{\nu}/2}} \frac{1}{\Gamma_p(\bar{\boldsymbol{\nu}}/2)} |\mathbf{R}|_{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \text{etr} \left(-\frac{1}{2} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{Z}^{-1} \right), \quad (303)$$

where we used Lemma (7.1) of this paper and Lemma 3 (v) of Blasques et al. 2021. For the expected value see Blasques et al. 2021, Theorem 26, (iv). Now define for better readability $\boldsymbol{\Omega} = \boldsymbol{\Sigma}_{Blasques}$. For the score w.r.t. $\boldsymbol{\Sigma}$ start from (301),

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (304)$$

$$= \left(\frac{\partial \log |\boldsymbol{\Omega}|_{\frac{\nu}{2}}}{\partial \text{vech}(\boldsymbol{\Omega})^\top} - \frac{1}{2} \frac{\partial \text{tr}(\boldsymbol{\Omega} \mathbf{R}^{-1})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \right) \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (305)$$

$$(7.8), (7.10) = \frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\boldsymbol{\nu}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} - \mathbf{R}^{-1} \right)^\top \mathbf{G} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (306)$$

$$(199) = \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\boldsymbol{\nu}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \mathbf{C} - \mathbf{R}^{-1} \mathbf{C} \right) \text{dg}(\mathbf{m}^{r''})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (307)$$

Now, using the definition of $\mathbf{\Omega}$ and $\mathbf{C}_\Omega = \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1/2}$ this reduces to

$$\text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}_\Omega^{-\top} \text{dg}(\boldsymbol{\nu}) \mathbf{C}_\Omega^{-1} \mathbf{C} - \mathbf{R}^{-1} \mathbf{C} \right) \text{dg}(\mathbf{m}^{r''})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (308)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{r''})^{1/2} \text{dg}(\boldsymbol{\nu}) \text{dg}(\mathbf{m}^{r''})^{1/2} - \mathbf{R}^{-1} \mathbf{C} \right) \text{dg}(\mathbf{m}^{r''})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (309)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) - \mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \right) \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (310)$$

$$= -\text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} - \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) \right) \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (311)$$

For the Fisher information matrix with respect to $\boldsymbol{\Sigma}$ we use Lemma ??,

$$\mathcal{I} = - \left(\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (312)$$

where the expectation, using Lemma 7.8 and Lemma 7.10, boils down to

$$\mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \quad (313)$$

$$= \mathbb{E} \left[\frac{\partial^2 \log |\boldsymbol{\Omega}|_{\frac{\nu}{2}}}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} - \frac{\partial^2 \frac{\text{tr}(\boldsymbol{\Omega} \mathbf{R}^{-1})}{2}}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \quad (314)$$

$$= -\frac{1}{2} \mathbf{G}^\top \left(\mathbf{C}_\Omega^{-\top} \otimes \mathbf{C}_\Omega^{-\top} \text{dg}(\boldsymbol{\nu}) \mathbf{C}_\Omega^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \quad (315)$$

$$= -\frac{1}{2} \mathbf{G}^\top \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{r''})^{1/2} \otimes \mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) \text{dg}(\mathbf{m}^{r''}) \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1/2} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1}. \quad (316)$$

and

$$\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \mathbf{G}^+ \left(\mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \otimes \mathbf{I} \right) \mathbf{F}^\top \left(\mathbf{G}^+ (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1}. \quad (317)$$

□

Commented out are the inverse Riesz type I distribution with attempts to derive its expected value theoretically.

7.7.4 Inverse Wishart

Theorem 7.8. *Let*

$$\mathbf{R} = (n - p - 1)\mathbf{C}\bar{\mathbf{B}}\bar{\mathbf{B}}^\top\mathbf{C}^\top, \quad (318)$$

then \mathbf{R} is said to follow a standardized inverse Wishart distribution denoted by $\mathbf{R} \sim i\mathcal{W}(\boldsymbol{\Sigma}, \mathbf{n})$. The probability density function of \mathbf{R} is

$$p(\mathbf{R}|\boldsymbol{\Sigma}, n) = \frac{(n - p - 1)^{np/2}}{2^{np/2}} \frac{1}{\Gamma_p(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{-\frac{n}{2}} \text{etr} \left(-\frac{1}{2}(n - p - 1)\mathbf{Z}^{-1} \right). \quad (319)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma}, \quad (320)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = -\frac{1}{2}\mathbf{G}^\top \text{vec} \left((n - p - 1)\mathbf{R}^{-1} - n\boldsymbol{\Sigma}^{-1} \right) \quad (321)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = -\frac{n}{2}\mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}. \quad (322)$$

Proof. Remember that the Inverse Wishart distribution is just a special case of the Inverse Riesz distribution, with all degree of freedom parameters being equal,

$$n_1, \dots, n_p = n. \quad (323)$$

Using this, the probability density function is easily obtained from (293).³⁰ The expected value remains the same as for the Inverse Riesz type II.³¹ For the score, start from (306),

30. See also Kollo and Rosen 2005, Corollary 2.4.6.1.

31. See also Kollo and Rosen 2005, Corollary 2.4.14.

observe that for $n_1, \dots, n_p = n$, $\mathbf{\Omega} = (n - p - 1)\mathbf{\Sigma}$ to arrive at

$$\frac{\log p(\mathbf{R}|\mathbf{\Sigma}, n)}{\partial \text{vech}(\mathbf{\Sigma})^\top} = \frac{1}{2} \text{vec} \left(\frac{n}{n-p-1} \mathbf{\Sigma}^{-1} - \mathbf{R}^{-1} \right)^\top \mathbf{G} \frac{\partial \text{vech}(\mathbf{\Omega})}{\partial \text{vech}(\mathbf{\Sigma})^\top} \quad (324)$$

$$= \frac{1}{2} \text{vec} (n\mathbf{\Sigma}^{-1} - (n-p-1)\mathbf{R}^{-1})^\top \mathbf{G} \quad (325)$$

For the Fisher information matrix simply start from the equation above to obtain

$$\frac{\partial^2 \log p(\mathbf{R}|\mathbf{\Sigma}, n)}{\partial \text{vech}(\mathbf{\Sigma}) \partial \text{vech}(\mathbf{\Sigma})^\top} = \frac{n}{2} \frac{\partial \mathbf{G}^\top \text{vec}(\mathbf{\Sigma}^{-1})}{\partial \text{vech}(\mathbf{\Sigma})^\top} \quad (326)$$

$$= \frac{n}{2} \mathbf{G}^\top \mathbf{G} \frac{\partial \text{vech}(\mathbf{\Sigma}^{-1})^\top}{\partial \text{vech}(\mathbf{\Sigma})^\top} \quad (327)$$

$$\text{Lemma 7.7:} = -\frac{n}{2} \mathbf{G}^\top \mathbf{G} \mathbf{G}^+ (\mathbf{\Sigma}^{-1} \otimes \mathbf{\Sigma}^{-1}) \mathbf{G} \quad (328)$$

$$= -\frac{n}{2} \mathbf{G}^\top (\mathbf{\Sigma}^{-1} \otimes \mathbf{\Sigma}^{-1}) \mathbf{G}. \quad (329)$$

$$(330)$$

Commented out are the derivation of the dispersion matrix and the score scaled by the inverse Fisher Information Matrix and by the Dispersion Matrix (which do not reduce to simple GARCH dynamics as for the Riesz and Wishart).

□

7.7.5 t-Riesz

Theorem 7.9. *Let*

$$\mathbf{R} = \frac{\nu - 2}{\nu} \Gamma_{\left(\frac{\nu}{2}, \frac{2}{\nu}\right)}^{-1} \mathbf{C} \text{dg}(\mathbf{n})^{-\frac{1}{2}} \mathbf{B} \mathbf{B}^\top \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top, \quad (331)$$

then \mathbf{R} is said to follow a standardized *t*-Riesz distribution of type I denoted by $\mathbf{R} \sim t\mathcal{R}^I(\boldsymbol{\Sigma}, \mathbf{n})$. The probability density function of \mathbf{R} is

$$p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}) = \frac{\prod_{i=1}^p n_i^{n_i/2} \Gamma((\nu + p\bar{\mathbf{n}})/2)}{(\nu - 2)^{p\bar{\mathbf{n}}/2} \Gamma_p(\mathbf{n}/2) \Gamma(\nu/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} \left(1 + \frac{1}{\nu - 2} \text{tr}(\text{dg}(\mathbf{n})\mathbf{Z})\right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}}. \quad (332)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} \quad (333)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\frac{\nu + p\bar{\mathbf{n}}}{\nu - 2 + \text{tr}(\text{dg}(\mathbf{n})\mathbf{Z})} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \right) \right) \mathbf{C}^{-1} \right) \quad (334)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = - \left(\frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top}, \quad (335)$$

with

$$\begin{aligned} \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] &= -\frac{1}{2} \left(\frac{\nu - 2}{\nu} \right)^2 \mathbf{G}^\top \left(\mathbf{C} \text{dg}(\mathbf{n})^{1/2} \otimes \mathbf{I} \right) \mathbf{F}^\top \\ &\quad \times \left(\mathbf{G}^\top \left(\mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \otimes \mathbf{I} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top \left(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \otimes \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right) \\ &\quad + \frac{1}{2} \left(\frac{\nu - 2}{\nu} \right)^2 \frac{1}{\nu + p\bar{\mathbf{n}} + 2} \mathbf{G}^\top \left(2 \left(\boldsymbol{\Sigma} \otimes \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \end{aligned}$$

and

$$\frac{\partial \text{vech}(\mathbf{\Omega}^{-1})}{\partial \text{vech}(\mathbf{\Sigma})^\top} \quad (336)$$

$$= -\frac{\nu}{\nu-2} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ \left(\mathbf{\Sigma}^{-1} \otimes \mathbf{\Sigma}^{-1} \right) \mathbf{G}. \quad (337)$$

Proof. Define $\mathbf{\Omega} = (\nu - 2)/\nu \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top$, $\mathbf{A} = \mathbf{C} \mathbf{\Omega} \mathbf{B} \mathbf{B}^\top \mathbf{C}^\top$, which implies that $\mathbf{A} \sim \mathcal{R}^I(\mathbf{\Omega}, \mathbf{n})$, and let $w \sim \Gamma(\frac{\nu}{2}, \frac{2}{\nu})$. Then we can rewrite $\mathbf{R} = w^{-1} \mathbf{A}$ with probability density function

$$p_{t\mathcal{R}^I}(\mathbf{R}|\mathbf{\Omega}, \mathbf{n}, \nu) = \int_0^\infty p_\Gamma\left(w \left| \frac{\nu}{2}, \frac{2}{\nu} \right.\right) p_{\mathcal{R}^I}(w\mathbf{R}|\mathbf{\Omega}, \mathbf{n}) J(w\mathbf{R} \rightarrow \mathbf{R}) dw \quad (338)$$

$$= \int_0^\infty \frac{1}{\Gamma(\frac{\nu}{2}) \left(\frac{2}{\nu}\right)^{\frac{\nu}{2}}} w^{\frac{\nu}{2}-1} e^{-w\frac{\nu}{2}} \frac{|w\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} e^{-\frac{\text{tr}(\mathbf{\Omega}^{-1}w\mathbf{R})}{2}}}{|\mathbf{\Omega}|_{\frac{\mathbf{n}}{2}} \Gamma_p\left(\frac{\mathbf{n}}{2}\right) 2^{\frac{p\bar{\mathbf{n}}}{2}}} w^{\frac{p(p+1)}{2}}} dw \quad (339)$$

$$= \frac{|\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} \int_0^\infty w^{\frac{\nu}{2}-1-p(p+1)/2+p\bar{\mathbf{n}}/2+p(p+1)/2} \exp\left[-w\frac{\nu}{2} \left(1 + \frac{\text{tr}(\mathbf{\Omega}^{-1}\mathbf{R})}{\nu}\right)\right] dw}{\Gamma(\frac{\nu}{2}) \left(\frac{2}{\nu}\right)^{\frac{\nu}{2}} |\mathbf{\Omega}|_{\frac{\mathbf{n}}{2}} \Gamma_p\left(\frac{\mathbf{n}}{2}\right) 2^{\frac{p\bar{\mathbf{n}}}{2}}} } \quad (340)$$

$$= \frac{|\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}}}{\Gamma(\frac{\nu}{2}) \left(\frac{2}{\nu}\right)^{\frac{\nu}{2}} |\mathbf{\Omega}|_{\frac{\mathbf{n}}{2}} \Gamma_p\left(\frac{\mathbf{n}}{2}\right) 2^{\frac{p\bar{\mathbf{n}}}{2}}} } \int_0^\infty w^{(\nu+p\bar{\mathbf{n}})/2-1} \exp\left[-w\frac{\nu}{2} \left(1 + \frac{\text{tr}(\mathbf{\Omega}^{-1}\mathbf{R})}{\nu}\right)\right] dw \quad (341)$$

$$= \frac{|\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}}}{\Gamma(\frac{\nu}{2}) \left(\frac{2}{\nu}\right)^{\frac{\nu}{2}} |\mathbf{\Omega}|_{\frac{\mathbf{n}}{2}} \Gamma_p\left(\frac{\mathbf{n}}{2}\right) 2^{\frac{p\bar{\mathbf{n}}}{2}}} } \Gamma((\nu+p\bar{\mathbf{n}})/2) \left[\frac{\nu}{2} \left(1 + \frac{\text{tr}(\mathbf{\Omega}^{-1}\mathbf{R})}{\nu}\right)\right]^{-\frac{\nu+p\bar{\mathbf{n}}}{2}} \quad (342)$$

$$= \frac{\Gamma((\nu+p\bar{\mathbf{n}})/2)}{\Gamma(\frac{\nu}{2}) \Gamma_p\left(\frac{\mathbf{n}}{2}\right) \nu^{p\bar{\mathbf{n}}/2}} |\mathbf{\Omega}|_{-\frac{\mathbf{n}}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{\text{tr}(\mathbf{\Omega}^{-1}\mathbf{R})}{\nu}\right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}}, \quad (343)$$

where we used <https://dlmf.nist.gov/5.9#i>. Now substituting $\mathbf{\Omega}$ with its definition we

get the standardized probability density function

$$p_{t\mathcal{R}^I}(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \nu) = \frac{\Gamma((\nu + p\bar{\mathbf{n}})/2)}{\Gamma(\frac{\nu}{2})\Gamma_p(\frac{\mathbf{n}}{2})\nu^{p\bar{\mathbf{n}}/2}} \left| \frac{\nu-2}{\nu} \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right|_{-\frac{\mathbf{n}}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{\text{tr} \left(\left(\frac{\nu-2}{\nu} \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right)^{-1} \mathbf{R} \right)}{\nu} \right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}} \quad (344)$$

$$= \frac{\Gamma((\nu + p\bar{\mathbf{n}})/2)}{\Gamma(\frac{\nu}{2})\Gamma_p(\frac{\mathbf{n}}{2})\nu^{p\bar{\mathbf{n}}/2}} \left(\frac{\nu-2}{\nu} \right)^{-p\bar{\mathbf{n}}/2} \left| \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right|_{-\frac{\mathbf{n}}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{\text{tr} \left(\left(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right)^{-1} \mathbf{R} \right)}{\nu-2} \right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}} \quad (345)$$

$$= \frac{\prod_{i=1}^p n_i^{n_i/2} \Gamma((\nu + p\bar{\mathbf{n}})/2)}{(\nu-2)^{p\bar{\mathbf{n}}/2} \Gamma_p(\mathbf{n}/2) \Gamma(\nu/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} \left(1 + \frac{1}{\nu-2} \text{tr}(\text{dg}(\mathbf{n})\mathbf{Z}) \right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}}. \quad (346)$$

For the expected value we have

$$\mathbb{E}[\mathbf{R}] = \mathbb{E} \left[\frac{1}{w} \right] \mathbb{E}[\mathbf{A}] = \mathbb{E} \left[\frac{1}{w} \right] \mathbf{C}_\Omega \mathbb{E}[\mathbf{B}\mathbf{B}^\top] \mathbf{C}_\Omega^\top \quad (347)$$

$$= \frac{\nu}{\nu-2} \mathbf{C}_\Omega \text{dg}(\mathbf{n}) \mathbf{C}_\Omega^\top \quad (348)$$

$$= \frac{\nu}{\nu-2} \frac{\nu-2}{\nu} \mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{n})^{-1/2} \mathbf{C}^\top \quad (349)$$

$$= \boldsymbol{\Sigma}, \quad (350)$$

where $\nu/(\nu-2)$ is the expectation of the inverse Gamma distribution.

For the score w.r.t. $\boldsymbol{\Sigma}$ consider again

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \nu)}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} \frac{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top}, \quad (351)$$

where starting from equation (345) we have

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \nu)}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} = \frac{\partial \log |\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top|_{-\frac{n}{2}}}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} - \frac{\nu + p\bar{\mathbf{n}}}{2} \frac{\partial \log \left(1 + \frac{\text{tr}((\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^{-1} \mathbf{R})}{\nu - 2} \right)}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} \quad (352)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n})^{1/2} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{n})^{1/2} \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (353)$$

$$- \frac{\nu + p\bar{\mathbf{n}}}{2} \frac{1}{\left(1 + \frac{\text{tr}((\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^{-1} \mathbf{R})}{\nu - 2} \right)} \frac{\partial \left(1 + \frac{\text{tr}((\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^{-1} \mathbf{R})}{\nu - 2} \right)}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} \quad (354)$$

$$= \text{vec} \left(-\frac{1}{2} \mathbf{C}^{-\top} \text{dg}(\mathbf{n})^2 \mathbf{C}^{-1} + \frac{\nu + p\bar{\mathbf{n}}}{2} \frac{1}{\left(1 + \frac{\text{tr}(\text{dg}(\mathbf{n}) \mathbf{Z})}{\nu - 2} \right)} \frac{1}{\nu - 2} \left(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \right)^{-1} \mathbf{R} \right) \quad (355)$$

$$= \text{vec} \left(-\frac{1}{2} \mathbf{C}^{-\top} \text{dg}(\mathbf{n})^2 \mathbf{C}^{-1} + \frac{\nu + p\bar{\mathbf{n}}}{2} \frac{1}{\left(1 + \frac{\text{tr}(\text{dg}(\mathbf{n}) \mathbf{Z})}{\nu - 2} \right)} \frac{1}{\nu - 2} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \quad (356)$$

$$= \frac{1}{2} \text{vec} \left(\frac{\nu + p\bar{\mathbf{n}}}{(\nu - 2 + \text{tr}(\text{dg}(\mathbf{n}) \mathbf{Z}))} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n})^2 \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (357)$$

Now, using (199) we have

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n})}{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)^\top} \frac{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (358)$$

$$= \frac{1}{2} \text{vec} \left(\frac{\nu + p\bar{\mathbf{n}}}{(\nu - 2 + \text{tr}(\text{dg}(\mathbf{n})\mathbf{Z}))} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n})^2 \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (359)$$

$$\times \frac{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (360)$$

$$= \mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\frac{\nu + p\bar{\mathbf{n}}}{\nu - 2 + \text{tr}(\text{dg}(\mathbf{n})\mathbf{Z})} \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{Z} - \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \right) \right) \mathbf{C}^{-1} \right). \quad (361)$$

For the Fisher information matrix w.r.t. $\boldsymbol{\Sigma}$ we will again use $\boldsymbol{\Omega}$ as defined above and note that

$$\frac{\partial^2 \log \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} = \frac{\partial}{\partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \left[\left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-1} \frac{\partial \text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1})} \right] \quad (362)$$

$$= -\frac{1}{\nu^2} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-2} \frac{\partial \text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1})} \frac{\partial \text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \quad (363)$$

$$= -\frac{1}{\nu^2} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-2} \mathbf{G}^\top \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top \mathbf{G}. \quad (364)$$

We will need the expectation of this expression. For better overview denote the normalizing constant of the t -Riesz distribution by

$$c(\nu, \mathbf{n}, \boldsymbol{\Omega}) = \frac{\Gamma((\nu + p\bar{\mathbf{n}})/2)}{\Gamma(\nu/2) \Gamma_p(\mathbf{n}/2) \nu^{p\bar{\mathbf{n}}/2} |\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}}. \quad (365)$$

Then

$$\mathbb{E} \left[\left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-2} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top \right] \quad (366)$$

$$= c(\nu, \mathbf{n}, \boldsymbol{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-2} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top |\mathbf{R}|^{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-\frac{\nu+p\bar{\mathbf{n}}}{2}} d\mathbf{R} \quad (367)$$

$$= c(\nu, \mathbf{n}, \boldsymbol{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top |\mathbf{R}|^{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1} \mathbf{R})}{\nu} \right)^{-\frac{\nu+p\bar{\mathbf{n}}+4}{2}} d\mathbf{R} \quad (368)$$

$$= c(\nu, \mathbf{n}, \boldsymbol{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top |\mathbf{R}|^{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{1}{\nu+4} \text{tr} \left(\left(\frac{\nu}{\nu+4} \boldsymbol{\Omega} \right)^{-1} \mathbf{R} \right) \right)^{-\frac{\nu+p\bar{\mathbf{n}}+4}{2}} d\mathbf{R} \quad (369)$$

$$= \frac{c(\nu, \mathbf{n}, \boldsymbol{\Omega})}{c\left(\nu+4, \mathbf{n}, \frac{\nu}{\nu+4} \boldsymbol{\Omega}\right)} \underbrace{\times c\left(\nu+4, \mathbf{n}, \frac{\nu}{\nu+4} \boldsymbol{\Omega}\right) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top |\mathbf{R}|^{\frac{\mathbf{n}-p-1}{2}} \left(1 + \frac{1}{\nu+4} \text{tr} \left(\left(\frac{\nu}{\nu+4} \boldsymbol{\Omega} \right)^{-1} \mathbf{R} \right) \right)^{-\frac{\nu+p\bar{\mathbf{n}}+4}{2}} d\mathbf{R}}_{\mathbb{E}[\text{vec}(\mathbf{R})\text{vec}(\mathbf{R})^\top] \text{ if } \mathbf{R} \text{ follows a } t\text{-Riesz distribution with parameters } \nu+4, \mathbf{n} \text{ and } \boldsymbol{\Omega}_{new} = \frac{\nu}{\nu+4} \boldsymbol{\Omega}} \quad (370)$$

$$= \frac{c(\nu, \mathbf{n}, \boldsymbol{\Omega})}{c\left(\nu+4, \mathbf{n}, \frac{\nu}{\nu+4} \boldsymbol{\Omega}\right)} \frac{(\nu+4)^2}{(\nu+2)\nu} \left(\frac{\nu}{\nu+4} \right)^2 \quad (371)$$

$$\times \mathbf{G}\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}\mathbf{G}^+)^\top \quad (372)$$

$$= \frac{\Gamma((\nu+p\bar{\mathbf{n}})/2) \Gamma_p(\mathbf{n}/2) \Gamma((\nu+4)/2) (\nu+4)^{p\bar{\mathbf{n}}/2}}{\Gamma_p(\mathbf{n}/2) \Gamma(\nu/2) \Gamma((\nu+4)+p\bar{\mathbf{n}})/2} \frac{(\nu+4)^{p\bar{\mathbf{n}}/2}}{\nu^{p\bar{\mathbf{n}}/2}} \left(\frac{\nu+4}{\nu} \right)^{-p\bar{\mathbf{n}}/2} \frac{|\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}}{|\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}} \frac{\nu}{\nu+2} \times \mathbf{G}\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}\mathbf{G}^+)^\top \quad (373)$$

$$= \frac{\nu(\nu+2)}{(\nu+p\bar{\mathbf{n}})(\nu+p\bar{\mathbf{n}}+2)} \frac{\nu}{\nu+2} \quad (374)$$

$$\times \mathbf{G}\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}\mathbf{G}^+)^\top \quad (375)$$

$$= \frac{\nu^2}{(\nu+p\bar{\mathbf{n}})(\nu+p\bar{\mathbf{n}}+2)} \quad (376)$$

$$\times \mathbf{G}\mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}\mathbf{G}^+)^\top \quad (377)$$

with

$$\mathbf{Cov}(\text{vech}(\mathbf{R})) = \mathbb{E} \left[\frac{1}{w^2} \right] \mathbf{Cov}(\text{vech}(\mathbf{A})) + \mathbf{Var} \left(\frac{1}{w} \right) \mathbb{E}[\text{vech}(\mathbf{A})] \mathbb{E}[\text{vech}(\mathbf{A})^\top] \quad (379)$$

$$= 2 \frac{\nu^2}{(\nu-2)(\nu-4)} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}^+)^\top \quad (380)$$

$$+ 2 \frac{\nu^2}{(\nu-4)(\nu-2)^2} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) (\mathbf{G}^+)^\top, \quad (381)$$

where

$$\mathbf{Var} \left(\frac{1}{w} \right) = \frac{(\nu/2)^2}{(\nu/2-1)^2(\nu/2-2)} = 2 \frac{\nu^2}{(\nu-2)^2(\nu-4)} \quad (382)$$

and

$$\mathbb{E} \left[\frac{1}{w^2} \right] = \mathbf{Var} \left(\frac{1}{w} \right) + \mathbb{E} \left[\frac{1}{w} \right]^2 = \left(\frac{\nu}{\nu-2} \right)^2 + 2 \frac{\nu^2}{(\nu-2)^2(\nu-4)} \quad (383)$$

$$= \left(\frac{\nu}{\nu-2} \right)^2 \left(1 + \frac{2}{\nu-4} \right) = \left(\frac{\nu}{\nu-2} \right)^2 \frac{\nu-2}{\nu-4} = \frac{\nu^2}{(\nu-2)(\nu-4)}. \quad (384)$$

Thus

$$\mathbb{E} \left[\text{vech}(\mathbf{R}) \text{vech}(\mathbf{R})^\top \right] = \mathbf{Cov}(\text{vech}(\mathbf{R})) + \mathbb{E}[\text{vech}(\mathbf{R})] \mathbb{E}[\text{vech}(\mathbf{R})^\top] \quad (385)$$

$$= 2 \frac{\nu^2}{(\nu-2)(\nu-4)} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) (\text{dg}(\mathbf{n}) \otimes \mathbf{I}) \left(\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top \right) (\mathbf{G}^+)^\top \quad (386)$$

$$+ 2 \frac{\nu^2}{(\nu-4)(\nu-2)^2} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \left(\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top \right) (\mathbf{G}^+)^\top \quad (387)$$

$$+ 2 \left(\frac{\nu}{\nu-2} \right)^2 \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \left(\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top \right) (\mathbf{G}^+)^\top \quad (388)$$

$$= \frac{\nu^2}{(\nu-2)(\nu-4)} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \quad (389)$$

$$\times \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) \left(\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top \right) (\mathbf{G}^+)^\top. \quad (390)$$

and consequently

$$\mathbb{E} \left[\text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top \right] = \mathbf{G} \mathbb{E} \left[\text{vech}(\mathbf{R}) \text{vech}(\mathbf{R})^\top \right] \mathbf{G}^\top \quad (391)$$

$$= \frac{\nu^2}{(\nu-2)(\nu-4)} \mathbf{G} \mathbf{G}^+ (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \quad (392)$$

$$\times \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) \left(\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top \right) (\mathbf{G} \mathbf{G}^+)^\top. \quad (393)$$

Using the results above we have

$$\mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] = \frac{\partial^2 \log |\boldsymbol{\Omega}|_{-\frac{n}{2}}}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} - \frac{\nu + p\bar{n}}{2} \mathbb{E} \left[\frac{\partial^2 \log \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1}\mathbf{R})}{\nu} \right)}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] \quad (394)$$

$$= \frac{\partial^2 \log |\boldsymbol{\Omega}|_{-\frac{n}{2}}}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} + \frac{\nu + p\bar{n}}{2} \frac{1}{\nu^2} \mathbf{G}^\top \mathbb{E} \left[\left(1 + \frac{\text{tr}(\boldsymbol{\Omega}^{-1}\mathbf{R})}{\nu} \right)^{-2} \text{vec}(\mathbf{R}) \text{vec}(\mathbf{R})^\top \right] \mathbf{G} \quad (395)$$

$$= \frac{\partial^2 \log |\boldsymbol{\Omega}|_{-\frac{n}{2}}}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} + \frac{\nu + p\bar{n}}{2} \frac{1}{\nu^2} \frac{\nu^2}{(\nu + p\bar{n})(\nu + p\bar{n} + 2)} \times \mathbf{G}^\top (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) \mathbf{G} \quad (396)$$

$$= \frac{\partial^2 \log |\boldsymbol{\Omega}|_{-\frac{n}{2}}}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} + \frac{1}{2} \frac{1}{\nu + p\bar{n} + 2} \mathbf{G}^\top (\mathbf{C}_\Omega \otimes \mathbf{C}_\Omega) \left(2(\text{dg}(\mathbf{n}) \otimes \mathbf{I}) + \text{vec}(\text{dg}(\mathbf{n})) \text{vec}(\text{dg}(\mathbf{n}))^\top \right) (\mathbf{C}_\Omega^\top \otimes \mathbf{C}_\Omega^\top) \mathbf{G} \quad (397)$$

$$= -\frac{1}{2} \mathbf{G}^\top (\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^\top (\mathbf{C}_\Omega \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top (\boldsymbol{\Omega} \otimes \boldsymbol{\Omega}) \mathbf{G} + \frac{1}{2} \frac{1}{\nu + p\bar{n} + 2} \mathbf{G}^\top \left(2(\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \mathbf{C}_\Omega^\top \otimes \boldsymbol{\Omega}) + \text{vec}(\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \mathbf{C}_\Omega^\top) \text{vec}(\mathbf{C}_\Omega \text{dg}(\mathbf{n}) \mathbf{C}_\Omega^\top)^\top \right) \mathbf{G} \quad (398)$$

$$= -\frac{1}{2} \left(\frac{\nu - 2}{\nu} \right)^2 \mathbf{G}^\top (\mathbf{C} \text{dg}(\mathbf{n})^{1/2} \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^\top (\mathbf{C} \text{dg}(\mathbf{n})^{-1/2} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top (\mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top \otimes \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top) \mathbf{G} + \frac{1}{2} \left(\frac{\nu - 2}{\nu} \right)^2 \frac{1}{\nu + p\bar{n} + 2} \mathbf{G}^\top \left(2(\boldsymbol{\Sigma} \otimes \mathbf{C} \text{dg}(\mathbf{n})^{-1} \mathbf{C}^\top) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \mathbf{G}, \quad (399)$$

such that using Lemma (??) we have

$$\mathcal{I} = - \left(\frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (400)$$

with

$$\frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = -\frac{\nu}{\nu-2} \mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \mathbf{C}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}^{-1} \right) \mathbf{F}^\top \left(\mathbf{G}^+ \left(\mathbf{C}^{-\top} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{F}^\top \right)^{-1} \mathbf{G}^+ \left(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1} \right) \mathbf{G}. \quad (401)$$

□

7.7.6 t-Wishart

Theorem 7.10. *Let*

$$\mathbf{R} = \frac{\nu - 2}{\nu n} \Gamma_{\left(\frac{\nu}{2}, \frac{2}{\nu}\right)}^{-1} \underline{\mathbf{B}} \underline{\mathbf{B}}^\top, \quad (402)$$

then \mathbf{R} is said to follow a standardized Wishart distribution based on the t -model (Sutradhar and Ali 1989), which we simply call t -Wishart distribution and denote by $\mathbf{R} \sim t\mathcal{W}(\boldsymbol{\Sigma}, n, \nu)$. The probability density function of \mathbf{R} is

$$f(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu) = \left(\frac{n}{\nu - 2}\right)^{pn/2} \frac{\Gamma((\nu + pn)/2)}{\Gamma_p(n/2) \Gamma(\nu/2)} |\boldsymbol{\Sigma}|^{-\frac{n}{2}} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{\frac{n}{2}} \left(1 + \frac{n}{\nu - 2} \text{tr}(\mathbf{Z})\right)^{-\frac{\nu+pn}{2}}. \quad (403)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma}, \quad (404)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \frac{1}{2} \mathbf{G}^\top \text{vec} \left(n \frac{\nu + pn}{\nu - 2 + n \text{tr}(\boldsymbol{\Sigma}^{-1} \mathbf{R})} \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1} \right), \quad (405)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = \frac{n}{2} \mathbf{G}^\top \left(\frac{\nu + pn}{\nu + pn + 2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{n}{\nu + pn + 2} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (406)$$

Proof. We base the proof on the standardized t -Riesz I distribution by setting $n_i = n$ for all i . The probability density function follows easily. The expected value is the same as for the t -Riesz I distribution since its independent of \mathbf{n} . For the score w.r.t. $\boldsymbol{\Sigma}$ start from equation (360) to get

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{1}{2} \text{vec} \left(\frac{\nu + pn}{\nu - 2 + n \text{tr}(\mathbf{Z})} n^2 \mathbf{C}^{-\top} \mathbf{Z} \mathbf{C}^{-1} - n^2 \boldsymbol{\Sigma}^{-1} \right)^\top \mathbf{G} n^{-1} \quad (407)$$

$$= \frac{1}{2} \text{vec} \left(\frac{\nu + pn}{\nu - 2 + n \text{tr}(\boldsymbol{\Sigma}^{-1} \mathbf{R})} n \boldsymbol{\Sigma}^{-1} \mathbf{R} \boldsymbol{\Sigma}^{-1} - n \boldsymbol{\Sigma}^{-1} \right)^\top \mathbf{G}. \quad (408)$$

For the Fisher information matrix w.r.t. $\boldsymbol{\Sigma}$ notice that if $n_i = n$ for all i equation (401)

reduces to

$$\mathcal{I} = - \left(\frac{n\nu}{\nu-2} \right)^2 \left(\frac{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (409)$$

with according to equation (399)

$$\mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1}) \partial \text{vech}(\boldsymbol{\Omega}^{-1})^\top} \right] \quad (410)$$

$$= -\frac{1}{2} \left(\frac{\nu-2}{\nu} \right)^2 n^{-1} \mathbf{G}^\top (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \left(\mathbf{G}^\top (\mathbf{C} \otimes \mathbf{I}) \mathbf{F}^\top \right)^{-1} \mathbf{G}^\top (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) \mathbf{G} \\ + \frac{1}{2} \left(\frac{\nu-2}{\nu} \right)^2 \frac{1}{\nu+pn+2} \mathbf{G}^\top \left(\frac{2}{n} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \mathbf{G} \quad (411)$$

$$= \frac{1}{2} \left(\frac{\nu-2}{\nu} \right)^2 \mathbf{G}^\top \left(-n^{-1} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \frac{1}{\nu+pn+2} \left(\frac{2}{n} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \right) \mathbf{G} \quad (412)$$

and

$$\frac{\partial \text{vech}(\boldsymbol{\Sigma}^{-1})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = -\mathbf{G}^+ (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}, \quad (413)$$

such that altogether

$$\mathcal{I} = - \left(\frac{n\nu}{\nu-2} \right)^2 (-\mathbf{G}^+ (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G})^\top \quad (414)$$

$$\times \frac{1}{2} \left(\frac{\nu-2}{\nu} \right)^2 \mathbf{G}^\top \left(-n^{-1} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \frac{1}{\nu+pn+2} \left(\frac{2}{n} (\boldsymbol{\Sigma} \otimes \boldsymbol{\Sigma}) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma})^\top \right) \right) \mathbf{G} \quad (415)$$

$$\times (-\mathbf{G}^+ (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G}) \quad (416)$$

$$= -\frac{1}{2} n^2 \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) (\mathbf{G}^+)^\top \mathbf{G}^\top \quad (417)$$

$$\times \left(-n^{-1} (\mathbf{I} \otimes \mathbf{I}) + \frac{1}{\nu+pn+2} \left(\frac{2}{n} (\mathbf{I} \otimes \mathbf{I}) + \text{vec}(\boldsymbol{\Sigma}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \right) \mathbf{G} \quad (418)$$

$$= -\frac{1}{2} \mathbf{G}^\top \left(-n (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + \frac{n^2}{\nu+pn+2} \left(\frac{2}{n} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \right) \mathbf{G} \quad (419)$$

$$= -\frac{n}{2} \mathbf{G}^\top \left(-(\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + \frac{2}{\nu+pn+2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + \frac{n}{\nu+pn+2} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G} \quad (420)$$

$$= \frac{n}{2} \mathbf{G}^\top \left(\frac{\nu+pn}{\nu+pn+2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{n}{\nu+pn+2} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (421)$$

Commented out are the stand-alone proofs, i.e. not based on the t-Riesz distribution.

□

7.7.7 Inverse t-Riesz

Theorem 7.11. *Let*

$$\mathbf{R} = \Gamma_{\left(\frac{n}{2}, \frac{2}{n}\right)} \mathbf{C} \text{dg}(\mathbf{m}^{\text{ru}})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{ru}})^{-\frac{1}{2}} \mathbf{C}^{\top}. \quad (422)$$

Then \mathbf{R} is said to follow a standardized inverse t-Riesz distribution of type II, denoted by $\mathbf{R} \sim i\mathcal{R}^{II}(\boldsymbol{\Sigma}, \mathbf{n}, \nu)$ with \mathbf{m}^{ru} given in (292). The probability density function of \mathbf{R} is

$$\begin{aligned} p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu) &= \frac{\prod_{i=1}^p (m_i^{\text{ru}})^{-\nu_i/2}}{n^{p\bar{\nu}/2}} \frac{\Gamma((n+p\bar{\nu})/2)}{\Gamma_p(\bar{\nu}/2)\Gamma(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \\ &\quad \times \left(1 + \frac{1}{n} \text{tr}(\text{dg}(\mathbf{m}^{\text{ru}})^{-1} \mathbf{Z}^{-1})\right)^{-\frac{n+p\bar{\nu}}{2}}. \end{aligned} \quad (423)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma}, \quad (424)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \mathbf{G}^{\top} \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^{\top} \mathbf{X} \right) \mathbf{C}^{-1} \right) \quad (425)$$

with

$$\mathbf{X} = \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) - \frac{n+p\bar{\nu}}{n + \text{tr}(\text{dg}(\mathbf{m}^{\text{ru}})^{-1} \mathbf{Z}^{-1})} \mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{\text{ru}})^{-1} \right).$$

Proof. For the probability density function, note that in the stochastic representation $\mathbf{A} = \mathbf{C} \text{dg}(\mathbf{m}^{\text{ru}})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{ru}})^{-\frac{1}{2}} \mathbf{C}^{\top} \sim i\mathcal{R}^{II}(\boldsymbol{\Sigma}, \boldsymbol{\nu})$ and denote $w \sim \Gamma_{\left(\frac{n}{2}, \frac{2}{n}\right)}$ such

that $\mathbf{R} = w\mathbf{A}$. Denote for better readability $\mathbf{\Omega} = \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{C}^\top$. Then

$$\begin{aligned}
p_{it\mathcal{R}II}(\mathbf{R}|\mathbf{\Sigma}, n, \nu) &= \int_0^\infty p_\Gamma\left(w \left| \frac{n}{2}, \frac{2}{n} \right.\right) p_{i\mathcal{R}II}(w^{-1}\mathbf{R}|\mathbf{\Sigma}, \nu) J(w^{-1}\mathbf{R} \rightarrow \mathbf{R}) dw \\
&= \int_0^\infty \frac{1}{\Gamma\left(\frac{n}{2}\right) \left(\frac{2}{n}\right)^{\frac{n}{2}}} w^{\frac{n}{2}-1} e^{-w\frac{n}{2}} \\
&\quad \times \frac{1}{2^{p\bar{\nu}/2} \Gamma_p\left(\frac{\bar{\nu}}{2}\right) |\mathbf{\Omega}|_{\frac{\nu}{2}} |w^{-1}\mathbf{R}|_{-\frac{\nu+p+1}{2}}} \text{etr}\left(-\frac{1}{2}w\mathbf{\Omega}\mathbf{R}^{-1}\right) \\
&\quad \times w^{-\frac{p(p+1)}{2}} dw \\
&= \frac{|\mathbf{\Omega}|_{\frac{\nu}{2}} |\mathbf{R}|_{-\frac{\nu+p+1}{2}}}{\Gamma\left(\frac{n}{2}\right) \left(\frac{2}{n}\right)^{\frac{n}{2}} 2^{p\bar{\nu}/2} \Gamma_p\left(\frac{\bar{\nu}}{2}\right)} \int_0^\infty w^{\frac{n+p\bar{\nu}}{2}-1} \exp\left(-w\frac{n}{2} \left(1 + \frac{\text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})}{n}\right)\right) dw \\
&= \frac{|\mathbf{\Omega}|_{\frac{\nu}{2}} |\mathbf{R}|_{-\frac{\nu+p+1}{2}}}{\Gamma\left(\frac{n}{2}\right) \left(\frac{2}{n}\right)^{\frac{n}{2}} 2^{p\bar{\nu}/2} \Gamma_p\left(\frac{\bar{\nu}}{2}\right)} \Gamma\left(\frac{n+p\bar{\nu}}{2}\right) \left(\frac{n}{2} \left(1 + \frac{\text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})}{n}\right)\right)^{-\frac{n+p\bar{\nu}}{2}} \\
&= \frac{1}{n^{p\bar{\nu}/2}} \frac{\Gamma\left(\frac{n+p\bar{\nu}}{2}\right)}{\Gamma\left(\frac{n}{2}\right) \Gamma_p\left(\frac{\bar{\nu}}{2}\right)} |\mathbf{\Omega}|_{\frac{\nu}{2}} |\mathbf{R}|_{-\frac{\nu+p+1}{2}} \left(1 + \frac{\text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})}{n}\right)^{-\frac{n+p\bar{\nu}}{2}} \\
&= \frac{\prod_{i=1}^p (m_i^{r''})^{-\nu_i/2}}{n^{p\bar{\nu}/2} |\mathbf{R}|_{\frac{p+1}{2}}} \frac{\Gamma((n+p\bar{\nu})/2)}{\Gamma_p(\bar{\nu}/2) \Gamma(n/2)} |\mathbf{Z}|_{-\frac{\nu}{2}} \left(1 + \frac{1}{n} \text{tr}(\text{dg}(\mathbf{m}^{r''})^{-1} \mathbf{Z}^{-1})\right)^{-\frac{n+p\bar{\nu}}{2}},
\end{aligned}$$

where we used <https://dlmf.nist.gov/5.9#i>. For the expected value note that when w follows a gamma distribution with $\gamma = \nu/2$ and $\beta = 2/\nu$, then $\mathbb{E}[w] = 1$ (Thom 1958). Furthermore recall that $\mathbb{E}[\mathbf{A}] = \mathbf{\Sigma}$, such that

$$\mathbb{E}[\mathbf{R}] = \mathbb{E}[w] \mathbb{E}[\mathbf{A}] = \mathbf{\Sigma}.$$

For the score we have

$$\begin{aligned}
\frac{\partial \log p_{it\mathcal{R}II}(\mathbf{R}|\mathbf{\Sigma}, n, \nu)}{\partial \text{vech}(\mathbf{\Omega})^\top} &= \frac{\partial \log |\mathbf{\Omega}|_{\frac{\nu}{2}}}{\partial \text{vech}(\mathbf{\Omega})} - \frac{n+p\bar{\nu}}{2} \frac{1/n}{1 + 1/n \text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})} \frac{\partial \text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})}{\partial \text{vech}(\mathbf{\Omega})} \\
&= \text{vec}\left(\frac{1}{2} \mathbf{C}_\Omega^{-\top} \text{dg}(\nu) \mathbf{C}_\Omega^{-1} - \frac{n+p\bar{\nu}}{2} \frac{1}{n + \text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})} \mathbf{R}^{-1}\right)^\top \mathbf{G} \\
&= \frac{1}{2} \text{vec}\left(\mathbf{C}^{-\top} \text{dg}(\nu \odot \mathbf{m}^{r''}) \mathbf{C}^{-1} - \frac{n+p\bar{\nu}}{n + \text{tr}(\mathbf{\Omega}\mathbf{R}^{-1})} \mathbf{R}^{-1}\right)^\top \mathbf{G}, \tag{426}
\end{aligned}$$

such that using Lemma 7.14 we have

$$\begin{aligned} \frac{\partial \log p_{it\mathcal{R}^{II}}(\mathbf{R}|\boldsymbol{\Sigma}, n, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} &= \frac{\partial \log p_{it\mathcal{R}^{II}}(\mathbf{R}|\boldsymbol{\Sigma}, n, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \\ &= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \mathbf{X} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \end{aligned} \quad (427)$$

with

$$\begin{aligned} \mathbf{X} &= \text{tril} \left(\left(\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu} \odot \mathbf{m}^{r^{II}}) \mathbf{C}^{-1} - \frac{n + p\bar{\nu}}{n + \text{tr}(\boldsymbol{\Omega}\mathbf{R}^{-1})} \mathbf{R}^{-1} \right) \mathbf{C} \right) \text{dg}(\mathbf{m}^{r^{II}})^{-1} \\ &= \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) - \frac{n + p\bar{\nu}}{n + \text{tr}(\text{dg}(\mathbf{m}^{r^{II}})^{-1} \mathbf{Z}^{-1})} \mathbf{R}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{r^{II}})^{-1} \right). \end{aligned}$$

For the Fisher information matrix, proceed similarly as for the inverse t-Wishart distribution, where first $\mathbb{E} \left[\text{vech}(\mathbf{R}) \text{vech}(\mathbf{R})^\top \right]$ for $\mathbf{R} \sim t\mathcal{R}^{II}$ has to be derived similarly to the expectation in $\mathbf{R} \sim t\mathcal{R}^I$.

□

7.7.8 Inverse t-Wishart

Theorem 7.12. *Let*

$$\mathbf{R} = (\nu - p - 1)\Gamma\left(\frac{n}{2}, \frac{2}{n}\right)\mathbf{C}\bar{\mathbf{B}}^{-\top}\bar{\mathbf{B}}^{-1}\mathbf{C}^\top. \quad (428)$$

Then \mathbf{R} is said to follow a standardized inverse t-Wishart distribution denoted by $\mathbf{R} \sim it\mathcal{W}(\boldsymbol{\Sigma}, n, \nu)$. Denote $\boldsymbol{\Omega} = (\nu - p - 1)\boldsymbol{\Sigma}$. The probability density function of \mathbf{R} is

$$p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu) = \left(\frac{\nu - p - 1}{n}\right)^{\nu p/2} \frac{\Gamma((n + p\nu)/2)}{\Gamma_p(\nu/2)\Gamma(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{-\frac{\nu}{2}} \left(1 + \frac{\nu - p - 1}{n} \text{tr}(\mathbf{Z}^{-1})\right)^{-\frac{n+p\nu}{2}} \quad (429)$$

$$= \frac{\Gamma((n + p\nu)/2)}{n^{\nu p/2}\Gamma_p(\nu/2)\Gamma(n/2)} |\boldsymbol{\Omega}|^{\frac{\nu}{2}} |\mathbf{R}|^{-\frac{\nu+p+1}{2}} \left(1 + \frac{\text{tr}(\boldsymbol{\Omega}\mathbf{R}^{-1})}{n}\right)^{-\frac{n+p\nu}{2}}, \quad (430)$$

the expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} = \frac{1}{\nu - p - 1}\boldsymbol{\Omega}, \quad (431)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \frac{1}{2}\mathbf{G}^\top \text{vec} \left(\nu\boldsymbol{\Sigma}^{-1} - \frac{(n + p\nu)(\nu - p - 1)}{n + (\nu - p - 1)\text{tr}(\boldsymbol{\Sigma}\mathbf{R}^{-1})}\mathbf{R}^{-1} \right) \quad (432)$$

and the Fisher Information Matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = -\frac{\nu}{2}\mathbf{G}^\top \left(\frac{n + p\nu}{n + p\nu + 2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{\nu}{(n + p\nu + 2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (433)$$

Proof. We base the proof on the standardized inverse t-Riesz II distribution by setting $\nu_i = \nu$ for all i . The probability density function and the expected value follow easily. For the score w.r.t. $\boldsymbol{\Sigma}$ use equations (426) and (427), and

$$\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = (\nu - p - 1)\mathbf{I} \quad (434)$$

to get

$$\frac{\partial \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \text{vec} \left(\frac{1}{2} \frac{\nu}{\nu - p - 1} \boldsymbol{\Sigma}^{-1} - \frac{n + p\nu}{2} \frac{1}{n + \text{tr}(\boldsymbol{\Omega}\mathbf{R}^{-1})} \mathbf{R}^{-1} \right)^\top \mathbf{G} (\nu - p - 1) \quad (435)$$

$$= \frac{1}{2} \text{vec} \left(\nu \boldsymbol{\Sigma}^{-1} - \frac{(n + p\nu)(\nu - p - 1)}{n + (\nu - p - 1)\text{tr}(\boldsymbol{\Sigma}\mathbf{R}^{-1})} \mathbf{R}^{-1} \right)^\top \mathbf{G}. \quad (436)$$

The proof of the Fisher information matrix w.r.t $\boldsymbol{\Sigma}$ follows closely the proof for the Fisher information matrix if the t-Wishart distribution. We have

$$\mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \quad (437)$$

$$= \frac{\nu}{2} \frac{\partial \log |\boldsymbol{\Omega}|}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} - \frac{n + p\nu}{2} \mathbb{E} \left[\frac{\partial^2 \log (1 + \frac{1}{n} \text{tr}(\boldsymbol{\Omega}\mathbf{R}^{-1}))}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \quad (438)$$

$$= -\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \mathbf{G} + \frac{n + p\nu}{2} \left(\frac{1}{n} \right)^2 \mathbf{G}^\top \mathbb{E} \left[\left(1 + \frac{1}{n} \text{tr}(\boldsymbol{\Omega}\mathbf{R}^{-1}) \right)^{-2} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top \right] \mathbf{G} \quad (439)$$

$$= -\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \mathbf{G} + \frac{n + p\nu}{2} \left(\frac{1}{n} \right)^2 \frac{n^2 \nu^2}{(n + p\nu)(n + p\nu + 2)} \frac{1}{(1)^2} \quad (440)$$

$$\times \mathbf{G}^\top \left(\text{vec}(\boldsymbol{\Omega}^{-1}) \text{vec}(\boldsymbol{\Omega}^{-1})^\top + \frac{2}{\nu} (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \right) \mathbf{G} \quad (441)$$

$$= -\frac{\nu}{2} \mathbf{G}^\top \left(\frac{n + p\nu}{n + p\nu + 2} (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) - \frac{\nu}{(n + p\nu + 2)} \text{vec}(\boldsymbol{\Omega}^{-1}) \text{vec}(\boldsymbol{\Omega}^{-1})^\top \right) \mathbf{G} \quad (442)$$

$$= -\frac{\nu}{2(n - p - 1)^2} \mathbf{G}^\top \left(\frac{n + p\nu}{n + p\nu + 2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{\nu}{(n + p\nu + 2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (443)$$

where

$$\frac{\partial^2 \log \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)}{\partial \text{vech}(\mathbf{\Omega}) \partial \text{vech}(\mathbf{\Omega})^\top} = \frac{\partial}{\partial \text{vech}(\mathbf{\Omega})^\top} \left[\left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-1} \frac{\partial \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1})}{\partial \text{vech}(\mathbf{\Omega})} \right] \quad (444)$$

$$= - \left(\frac{1}{n} \right)^2 \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-2} \frac{\partial \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1})}{\partial \text{vech}(\mathbf{\Omega})} \frac{\partial \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1})}{\partial \text{vech}(\mathbf{\Omega})^\top} \quad (445)$$

$$= - \left(\frac{1}{n} \right)^2 \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-2} \mathbf{G}^\top \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top \mathbf{G}, \quad (446)$$

and, denoting

$$c(n, \nu, \mathbf{\Omega}) = \frac{\Gamma((n + p\nu)/2)}{n^{p\nu/2} \Gamma_p(\nu/2) \Gamma(n/2)} |\mathbf{\Omega}|^{\frac{\nu}{2}}, \quad (447)$$

$$\mathbb{E} \left[\left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-2} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top \right] \quad (448)$$

$$= c(n, \nu, \mathbf{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-2} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top |\mathbf{R}|^{-\frac{\nu+p+1}{2}} \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-\frac{n+p\nu}{2}} d\mathbf{R} \quad (449)$$

$$= c(n, \nu, \mathbf{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top |\mathbf{R}|^{-\frac{\nu+p+1}{2}} \left(1 + \frac{1}{n} \text{tr}(\mathbf{\Omega} \mathbf{R}^{-1}) \right)^{-\frac{n+p\nu+4}{2}} d\mathbf{R} \quad (450)$$

$$= c(n, \nu, \mathbf{\Omega}) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top |\mathbf{R}|^{-\frac{\nu+p+1}{2}} \left(1 + \frac{1}{n+4} \text{tr} \left(\frac{n+4}{n} \mathbf{\Omega} \mathbf{R}^{-1} \right) \right)^{-\frac{n+p\nu+4}{2}} d\mathbf{R} \quad (451)$$

$$= \frac{c(n, \nu, \mathbf{\Omega})}{c(n+4, \nu, \frac{n+4}{n} \mathbf{\Omega})} \times \underbrace{c \left(n+4, \nu, \frac{n+4}{n} \mathbf{\Omega} \right) \int_{\mathbf{R} > \mathbf{0}} \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top |\mathbf{R}|^{-\frac{\nu+p+1}{2}} \left(1 + \frac{1}{n+4} \text{tr} \left(\frac{n+4}{n} \mathbf{\Omega} \mathbf{R}^{-1} \right) \right)^{-\frac{n+p\nu+4}{2}} d\mathbf{R}}_{\text{Expectation of } \text{vec}(\mathbf{R}^{-1}) \text{vec}(\mathbf{R}^{-1})^\top \text{ if } \mathbf{R} \text{ follows an inverse } t\text{-Wishart distribution with parameters } n+4, \nu \text{ and } \frac{n+4}{n} \mathbf{\Omega} \text{ or equivalent if } \mathbf{R}^{-1} \text{ follows a } t\text{-Wishart distribution with parameters } n+4, \nu \text{ and } \frac{n}{n+4} \mathbf{\Omega}^{-1} \text{ and that this expectation is given above.}} \quad (452)$$

$$= \frac{c(n, \nu, \mathbf{\Omega})}{c(n+4, \nu, \frac{n+4}{n} \mathbf{\Omega})} \frac{n\nu^2}{n+2} \left(\frac{1}{\nu} (\mathbf{I}_{p^2} + \mathbf{K}_{pp}) (\mathbf{\Omega}^{-1} \otimes \mathbf{\Omega}^{-1}) + \text{vec}(\mathbf{\Omega}^{-1}) \text{vec}(\mathbf{\Omega}^{-1})^\top \right) \quad (453)$$

$$= \frac{\Gamma((n+p\nu)/2)}{n^{p\nu/2} \Gamma_p(\nu/2) \Gamma(n/2)} |\mathbf{\Omega}^{-1}|^{\frac{\nu}{2}} \frac{(n+4)^{p\nu/2} \Gamma_p(\nu/2) \Gamma((n+4)/2)}{\Gamma((n+4+p\nu)/2)} \left| \frac{n}{n+4} \mathbf{\Omega}^{-1} \right|^{\frac{\nu}{2}} \frac{n\nu^2}{n+2} \times \left(\text{vec}(\mathbf{\Omega}^{-1}) \text{vec}(\mathbf{\Omega}^{-1})^\top + \frac{1}{\nu} (\mathbf{I}_{p^2} + \mathbf{K}_{pp}) (\mathbf{\Omega}^{-1} \otimes \mathbf{\Omega}^{-1}) \right) \text{ See iphone photo 22.06.2021} \quad (454)$$

$$= \frac{\Gamma((n+p\nu)/2)}{\Gamma((n+4+p\nu)/2)} \frac{\Gamma((n+4)/2)}{\Gamma(n/2)} \frac{n\nu^2}{n+2} \left(\text{vec}(\mathbf{\Omega}^{-1}) \text{vec}(\mathbf{\Omega}^{-1})^\top + \frac{1}{\nu} (\mathbf{I}_{p^2} + \mathbf{K}_{pp}) (\mathbf{\Omega}^{-1} \otimes \mathbf{\Omega}^{-1}) \right) \quad (455)$$

$$= \frac{n(n+2)}{(n+p\nu)(n+p\nu+2)} \frac{n\nu^2}{n+2} \left(\text{vec}(\mathbf{\Omega}^{-1}) \text{vec}(\mathbf{\Omega}^{-1})^\top + \frac{1}{\nu} (\mathbf{I}_{p^2} + \mathbf{K}_{pp}) (\mathbf{\Omega}^{-1} \otimes \mathbf{\Omega}^{-1}) \right) \quad (456)$$

$$= \frac{n^2\nu^2}{(n+p\nu)(n+p\nu+2)} \frac{1}{(1)^2} \left(\text{vec}(\mathbf{\Omega}^{-1}) \text{vec}(\mathbf{\Omega}^{-1})^\top + \frac{1}{\nu} (\mathbf{I}_{p^2} + \mathbf{K}_{pp}) (\mathbf{\Omega}^{-1} \otimes \mathbf{\Omega}^{-1}) \right). \quad (457)$$

Thus, finally

$$\mathcal{I} = \left(\frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \right)^\top \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, n)}{\partial \text{vech}(\boldsymbol{\Omega}) \partial \text{vech}(\boldsymbol{\Omega})^\top} \right] \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (458)$$

$$= -\frac{\nu(n-p-1)^2}{2(n-p-1)^2} \mathbf{G}^\top \left(\frac{n+p\nu}{n+p\nu+2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{\nu}{(n+p\nu+2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G} \quad (459)$$

$$= -\frac{\nu}{2} \mathbf{G}^\top \left(\frac{n+p\nu}{n+p\nu+2} (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - \frac{\nu}{(n+p\nu+2)} \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (460)$$

Commented out is the covariance matrix and the standalone derivation of score and expected value.

□

7.7.9 F-Riesz

Theorem 7.13. *Let*

$$\mathbf{R} = \mathbf{C} \text{dg}(\mathbf{m}^{\text{FR}'})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \mathbf{B} \mathbf{B}^\top \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{\text{FR}'})^{-\frac{1}{2}} \mathbf{C}^\top, \quad (461)$$

³² then \mathbf{R} is said to follow a standardized F-Riesz distribution of type I denoted by $\mathbf{R} \sim \mathcal{FR}^I(\boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu})$, with $\mathbf{m}^{\text{FR}'} = (m_1^{\text{FR}'}, m_2^{\text{FR}'}, \dots, m_p^{\text{FR}'})^\top$,

$$m_i^{\text{FR}'} = \begin{cases} \frac{n_1}{\nu_1 - p - 1}, & \text{for } i = 1 \\ \frac{1}{\nu_i - p + i - 2} \left(n_i + \sum_{i=1}^{i-1} m_i^{\text{FR}'} \right) & \text{for } i = 2, \dots, p. \end{cases} \quad (462)$$

Denote $\boldsymbol{\Omega} = \mathbf{C} \text{dg}(\mathbf{m}^{\text{FR}'})^{-1} \mathbf{C}^\top$. The probability density function of \mathbf{R} is

$$p(\mathbf{R} | \boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu}) = \prod_{i=1}^p (m_i^{\text{FR}'})^{n_i/2} \frac{\Gamma_p((\hat{\mathbf{n}} + \hat{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2) \Gamma_p(\hat{\boldsymbol{\nu}}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} \left| \mathbf{I}_p + \text{dg}(\mathbf{m}^{\text{FR}'})^{1/2} \mathbf{Z} \text{dg}(\mathbf{m}^{\text{FR}'})^{1/2} \right|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (463)$$

³³

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} = \mathbf{C} \boldsymbol{\Omega} \text{dg}(\mathbf{m}^{\text{FR}'}) \mathbf{C}^\top, \quad (464)$$

and the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \mathbf{G}^\top \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\boldsymbol{\nu}) - \mathbf{C}_{\boldsymbol{\Omega}+\mathbf{R}}^{-\top} \text{dg}(\boldsymbol{\nu} + \mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}+\mathbf{R}}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{\text{FR}'})^{-1} \right) \right) \mathbf{C}^{-1} \right). \quad (465)$$

Proof. Note that our stochastic representation is equivalent to the generation of the F-Riesz I distribution in Blasques et al. 2021 with $\boldsymbol{\Sigma}_{\text{Blasques}} = \boldsymbol{\Omega}$. For the probability

³². See photo 29.03.2021 for stochastic representation.

³³. Note that $|\mathbf{I}_p + \boldsymbol{\Omega}^{-1} \mathbf{R}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}}$ can not be calculated using the Cholesky-based calculation of the generalized power function, since $\mathbf{I}_p + \boldsymbol{\Omega}^{-1} \mathbf{R}$ is not symmetric positive definite.

density function we thus take their derived probability density function and rewrite

$$p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu}) = \frac{\Gamma_p^U((\mathbf{n} + \boldsymbol{\nu})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p^U(\boldsymbol{\nu}/2)} |\boldsymbol{\Omega}|_{\frac{\nu}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} |\boldsymbol{\Omega} + \mathbf{R}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (466)$$

$$= \frac{\Gamma_p^U((\mathbf{n} + \boldsymbol{\nu})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p^U(\boldsymbol{\nu}/2)} |\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} |\mathbf{I}_p + \boldsymbol{\Omega}^{-1}\mathbf{R}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (467)$$

$$= \prod_{i=1}^p (\mathbf{m}_i^{FR'})^{-\nu_i/2} \frac{\Gamma_p((\check{\mathbf{n}} + \check{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p(\check{\boldsymbol{\nu}}/2)} |\boldsymbol{\Sigma}|_{\frac{\nu}{2}} |\mathbf{R}|_{\frac{\mathbf{n}-p-1}{2}} |\mathbf{C} \text{dg}(\mathbf{m}^{FR'})^{-1} \mathbf{C}^\top + \mathbf{R}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (468)$$

$$= \prod_{i=1}^p (\mathbf{m}_i^{FR'})^{-\nu_i/2} \frac{\Gamma_p((\check{\mathbf{n}} + \check{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p(\check{\boldsymbol{\nu}}/2)} |\boldsymbol{\Sigma}|_{\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} |\mathbf{R}|^{-(p-1)/2} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} |\mathbf{C} \text{dg}(\mathbf{m}^{FR'})^{-1} \mathbf{C}^\top + \mathbf{R}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (469)$$

$$= \prod_{i=1}^p (\mathbf{m}_i^{FR'})^{-\nu_i/2} \frac{\Gamma_p((\check{\mathbf{n}} + \check{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p(\check{\boldsymbol{\nu}}/2)} |\mathbf{R}|^{-(p-1)/2} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} |\text{dg}(\mathbf{m}^{FR'})^{-1} + \mathbf{Z}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} \quad (470)$$

$$= \prod_{i=1}^p (\mathbf{m}_i^{FR'})^{-\nu_i/2} \frac{\Gamma_p((\check{\mathbf{n}} + \check{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p(\check{\boldsymbol{\nu}}/2)} |\text{dg}(\mathbf{m}^{FR'})|_{\frac{\mathbf{n}+\boldsymbol{\nu}}{2}} |\mathbf{R}|^{-(p-1)/2} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} |\mathbf{I} + \text{dg}(\mathbf{m}^{FR'})^{1/2} \mathbf{Z} \text{dg}(\mathbf{m}^{FR'})^{1/2}|_{-\mathbf{n}} \quad (471)$$

$$= \prod_{i=1}^p (\mathbf{m}_i^{FR'})^{n_i/2} \frac{\Gamma_p((\check{\mathbf{n}} + \check{\boldsymbol{\nu}})/2)}{\Gamma_p(\mathbf{n}/2)\Gamma_p(\check{\boldsymbol{\nu}}/2)} |\mathbf{R}|^{-(p-1)/2} |\mathbf{Z}|_{\frac{\mathbf{n}}{2}} |\mathbf{I} + \text{dg}(\mathbf{m}^{FR'})^{1/2} \mathbf{Z} \text{dg}(\mathbf{m}^{FR'})^{1/2}|_{-\frac{\mathbf{n}+\boldsymbol{\nu}}{2}}, \quad (472)$$

where we have used Lemma 7.4 and Blasques et al. 2021 Lemma 3 (v). For the expected value Blasques et al. 2021 derive in Theorem 10, that

$$\mathbb{E} \left[\bar{\mathbf{B}}^{-\top} \mathbf{B} \mathbf{B}^\top \bar{\mathbf{B}}^{-1} \right] = \text{dg}(\mathbf{m}^{FR'}), \quad (473)$$

such that

$$\mathbb{E} [\mathbf{R}] = \mathbf{C} \text{dg}(\mathbf{m}^{FR'})^{-\frac{1}{2}} \mathbb{E} \left[\bar{\mathbf{B}}^{-\top} \mathbf{B} \mathbf{B}^\top \bar{\mathbf{B}}^{-1} \right] \text{dg}(\mathbf{m}^{FR'})^{-\frac{1}{2}} \mathbf{C}^\top \quad (474)$$

$$= \mathbf{C} \text{dg}(\mathbf{m}^{FR'})^{-\frac{1}{2}} \text{dg}(\mathbf{m}^{FR'}) \text{dg}(\mathbf{m}^{FR'})^{-\frac{1}{2}} \mathbf{C}^\top = \boldsymbol{\Sigma}. \quad (475)$$

For the score w.r.t. Σ we have

$$\frac{\partial \log p(\mathbf{R}|\Sigma, \mathbf{n}, \nu)}{\partial \text{vech}(\Sigma)^\top} = \frac{\partial \log |\Omega|_{\frac{\nu}{2}}}{\partial \text{vech}(\Omega)^\top} + \frac{\partial \log |\Omega + \mathbf{R}|_{-\frac{\mathbf{n}+\nu}{2}}}{\partial \text{vech}(\Omega)^\top} \quad (476)$$

$$= \frac{\partial \log |\Omega|_{\frac{\nu}{2}}}{\partial \text{vech}(\Omega)^\top} + \frac{\partial \log |\Omega + \mathbf{R}|_{-\frac{\mathbf{n}+\nu}{2}}}{\partial \text{vech}(\Omega + \mathbf{R})^\top} \frac{\partial \text{vech}(\Omega + \mathbf{R})}{\partial \text{vech}(\Omega)^\top} \quad (477)$$

$$= \frac{1}{2} \text{vec} \left(\mathbf{C}_\Omega^{-\top} \text{dg}(\nu) \mathbf{C}_\Omega^{-1} \right)^\top \mathbf{G} - \frac{1}{2} \text{vec} \left(\mathbf{C}_{\Omega+\mathbf{R}}^{-\top} \text{dg}(\nu + \mathbf{n}) \mathbf{C}_{\Omega+\mathbf{R}}^{-1} \right)^\top \mathbf{G} \quad (478)$$

$$= \frac{1}{2} \text{vec} \left(\mathbf{C}^{-\top} \text{dg}(\nu \otimes \mathbf{m}^{r'}) \mathbf{C}^{-1} - \mathbf{C}_{\Omega+\mathbf{R}}^{-\top} \text{dg}(\nu + \mathbf{n}) \mathbf{C}_{\Omega+\mathbf{R}}^{-1} \right)^\top \mathbf{G}, \quad (479)$$

such that using Lemma 7.14

$$\frac{\partial \log p(\mathbf{R}|\Sigma, \mathbf{n}, \nu)}{\partial \text{vech}(\Sigma)^\top} \quad (480)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\left(\mathbf{C}^{-\top} \text{dg}(\nu \otimes \mathbf{m}^{r'}) \mathbf{C}^{-1} - \mathbf{C}_{\Omega+\mathbf{R}}^{-\top} \text{dg}(\nu + \mathbf{n}) \mathbf{C}_{\Omega+\mathbf{R}}^{-1} \right) \mathbf{C} \text{dg}(\mathbf{m}^{r'})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (481)$$

$$= \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\nu) - \mathbf{C}_{\Omega+\mathbf{R}}^{-\top} \text{dg}(\nu + \mathbf{n}) \mathbf{C}_{\Omega+\mathbf{R}}^{-1} \mathbf{C} \text{dg}(\mathbf{m}^{r'})^{-1} \right) \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}. \quad (482)$$

□

Note that it does not hold that $\mathbf{R} \sim \mathcal{FR}(\Omega^{-1}, \mathbf{n}, \nu) \Rightarrow \mathbf{R}^{-1} \sim \mathcal{FR}(\Omega, \nu, \mathbf{n})$ for either type.³⁴ This is in contrast to the F distribution. Also note that the standardized F-Riesz type *I* distribution cannot be obtained by mixing a standardized Riesz type *I* with a standardized inverse Riesz type *II*, but only by mixing the non-standardized versions and then standardizing the resulting distribution, as done above. This is also in contrast to the F distribution and can be seen, since

$$\mathbf{C} \text{dg}(\mathbf{m}^{r'})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \mathbf{B} \mathbf{B}^\top \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{r'})^{-\frac{1}{2}} \mathbf{C}^\top \quad (483)$$

$$\neq \mathbf{C} \text{dg}(\mathbf{m}^{r''})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \text{dg}(\mathbf{n})^{-\frac{1}{2}} \mathbf{B} \mathbf{B}^\top \text{dg}(\mathbf{n})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{r''})^{-\frac{1}{2}} \mathbf{C}^\top. \quad (484)$$

Commented out are the Hessian with some propositions for approximation of the Fisher

34. See the derivation of the inverse F-Riesz type *II* below. The derivation of the inverse F-Riesz type *I* is very similar.

information matrix, the derivation of the F -Riesz based on the Riesz type I and inverse Riesz type II, the derivation of the inverse F -Riesz type I distribution and an attempt to derive the distribution of $\mathbf{C} \text{dg}(\mathbf{m}^{ru})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-\top} \text{dg}(\mathbf{n})^{-\frac{1}{2}} \mathbf{B} \mathbf{B}^{\top} \text{dg}(\mathbf{n})^{-\frac{1}{2}} \bar{\mathbf{B}}^{-1} \text{dg}(\mathbf{m}^{ru})^{-\frac{1}{2}} \mathbf{C}^{\top}$.

7.7.10 Inverse F-Riesz

Theorem 7.14. *Let*

$$\mathbf{R} = \mathbf{C} \text{dg}(\mathbf{m}^{i\mathcal{R}II})^{-\frac{1}{2}} \mathbf{B} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \mathbf{B}^{\top} \text{dg}(\mathbf{m}^{i\mathcal{R}II})^{-\frac{1}{2}} \mathbf{C}^{\top}, \quad (485)$$

then \mathbf{R} is said to follow a standardized inverse F-Riesz distribution of type II denoted by $\mathbf{R} \sim i\mathcal{FR}^{II}(\boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu})$, with $\mathbf{m}^{i\mathcal{R}II} = (m_1^{i\mathcal{R}II}, \dots, m_p^{i\mathcal{R}II})^{\top}$ given by

$$m_i^{i\mathcal{R}II} = \begin{cases} n_1 m_1^{i\mathcal{R}II}, & \text{for } i = 1 \\ \sum_{j=1}^{i-1} m_j^{i\mathcal{R}II} + (n_i + i - 1) m_i^{i\mathcal{R}II}, & \text{for } i > 1, \end{cases} \quad (486)$$

The probability density function of \mathbf{R} is

$$p(\mathbf{R} | \boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu}) = \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathcal{R}II})^{n_i/2}}{\Gamma_p(\bar{\boldsymbol{\nu}}/2) \Gamma_p(\mathbf{n}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \left| (\text{dg}(\mathbf{m}^{i\mathcal{R}II}) + \mathbf{Z}^{-1})^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}}. \quad (487)$$

The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} \quad (488)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = -\mathbf{G}^{\top} \text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^{\top} \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) - \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i\mathcal{R}II}) \mathbf{C}^{-1} \mathbf{C}_{\mathbf{B}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{\mathbf{B}}^{\top} \mathbf{C}^{-\top} \right) \right) \mathbf{C}^{-1} \right), \quad (489)$$

where $\mathbf{B} = (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}$.

Proof. The stochastic representation \mathbf{Y} following an F-Riesz distribution of type II with scale matrix $\boldsymbol{\Omega}^{-1}$, and degree of freedom parameter vectors $\boldsymbol{\nu}$ and \mathbf{n} is $\mathbf{Y} = \mathbf{U}_{\boldsymbol{\Omega}^{-1}} \mathbf{B}^{-1} \bar{\mathbf{B}} \bar{\mathbf{B}}^{\top} \mathbf{B}^{-1} \mathbf{U}_{\boldsymbol{\Omega}^{-1}}^{\top}$, where $\mathbf{U}_{\boldsymbol{\Omega}^{-1}}$ is the upper Cholesky factor of $\boldsymbol{\Omega}^{-1}$.³⁵ Thus the stochastic representation of the inverse F-Riesz distribution of type II is given by

$$\mathbf{R} = \mathbf{Y}^{-1} = \mathbf{C}_{\boldsymbol{\Omega}} \mathbf{B} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \mathbf{B}^{\top} \mathbf{C}_{\boldsymbol{\Omega}}^{\top}, \quad (490)$$

35. See Blasques et al. 2021.

which translate to $\mathbf{R} \sim i\mathcal{R}^{II}(\mathbf{Y}, \nu)$, $\mathbf{Y} \sim \mathcal{R}^I(\Omega, \mathbf{n})$.³⁶ For the probability density function we can consequently use

$$p_{i\mathcal{R}^{II}}(\mathbf{R}|\Omega, \mathbf{n}, \nu) = \int_{\mathbf{Y}>\mathbf{0}} p_{i\mathcal{R}^{II}}(\mathbf{R}|\mathbf{Y}, \nu) p_{\mathcal{R}^I}(\mathbf{Y}|\Omega, \nu) d\mathbf{Y} \quad (491)$$

$$= \int_{\mathbf{Y}>\mathbf{0}} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\mathbf{Y}|_{\frac{\nu}{2}} \text{etr} \left(-\frac{1}{2} \mathbf{Y} \mathbf{R}^{-1} \right) \frac{1}{\Gamma_p(\bar{\nu}/2) 2^{p\bar{\nu}/2}} \quad (492)$$

$$\times |\mathbf{Y}|_{\frac{\mathbf{n}-p-1}{2}} |\Omega|_{-\frac{\mathbf{n}}{2}} \text{etr} \left(-\frac{1}{2} \Omega^{-1} \mathbf{Y} \right) \frac{1}{\Gamma_p(\mathbf{n}/2) 2^{p\bar{\mathbf{n}}/2}} d\mathbf{Y} \quad (493)$$

$$= \frac{1}{\Gamma_p(\bar{\nu}/2) \Gamma_p(\mathbf{n}/2) 2^{p\nu+\bar{\mathbf{n}}/2}} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\Omega|_{-\frac{\mathbf{n}}{2}} \int_{\mathbf{Y}>\mathbf{0}} |\mathbf{Y}|_{\frac{\mathbf{n}-p-1}{2}} \text{etr} \left(-\frac{1}{2} \mathbf{Y} (\Omega^{-1} + \mathbf{R}^{-1}) \right) d\mathbf{Y} \quad (494)$$

$$\text{Theorem 7.3:} = \frac{1}{\Gamma_p(\bar{\nu}/2) \Gamma_p(\mathbf{n}/2) 2^{p\nu+\bar{\mathbf{n}}/2}} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\Omega|_{-\frac{\mathbf{n}}{2}} 2^{p\nu+\bar{\mathbf{n}}/2} \Gamma_p((\nu + \mathbf{n})/2) \left| (\Omega^{-1} + \mathbf{R}^{-1})^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (495)$$

$$= \frac{\Gamma_p((\nu + \mathbf{n})/2)}{\Gamma_p(\bar{\nu}/2) \Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\Omega|_{-\frac{\mathbf{n}}{2}} \left| (\Omega^{-1} + \mathbf{R}^{-1})^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}}. \quad (496)$$

Now, it will be shown below that $\mathbb{E}[\mathbf{B}\bar{\mathbf{B}}^{-\top}\bar{\mathbf{B}}^{-1}\mathbf{B}^{\top}] = \text{dg}(\mathbf{m}^{i\mathcal{R}^{II}})$ is diagonal, such that $\Sigma =: \mathbb{E}[\mathbf{R}] = \mathbf{C}\Omega \text{dg}(\mathbf{m}^{i\mathcal{R}^{II}}) \mathbf{C}^{\top}$ and consequently $\Omega = \mathbf{C} \text{dg}(\mathbf{m}^{i\mathcal{R}^{II}})^{-1} \mathbf{C}^{\top}$. Finally the standardized inverse F-Riesz distribution of type *II* probability density function is then

36. Recall that $\mathbf{U}_{\Omega^{-1}}^{-\top} = \mathbf{C}\Omega$.

given by

$$p(\mathbf{R}|\boldsymbol{\Sigma}, \mathbf{n}, \boldsymbol{\nu}) = p_{\nu, \mathbf{R}^{ii}}(\mathbf{R}|\mathbf{C}\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}})^{-1}\mathbf{C}^\top, \mathbf{n}, \boldsymbol{\nu}) \quad (497)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2)}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\mathbf{C}\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}})^{-1}\mathbf{C}^\top|_{-\frac{\mathbf{n}}{2}} \left| \left(\left(\mathbf{C}\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}})^{-1}\mathbf{C}^\top \right)^{-1} + \mathbf{R}^{-1} \right)^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (498)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{n_i/2}}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\boldsymbol{\Sigma}|_{-\frac{\mathbf{n}}{2}} \left| \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) \mathbf{C}^{-1} + \mathbf{R}^{-1} \right)^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (499)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{n_i/2}}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\boldsymbol{\Sigma}|_{-\frac{\mathbf{n}}{2}} \left| \left(\mathbf{C}^{-\top} (\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) + \mathbf{Z}^{-1}) \mathbf{C}^{-1} \right)^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (500)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{n_i/2}}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|_{-\frac{\nu-p-1}{2}} |\boldsymbol{\Sigma}|_{-\frac{\mathbf{n}}{2}} \left| \mathbf{C} (\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) + \mathbf{Z}^{-1})^{-1} \mathbf{C}^\top \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (501)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{n_i/2}}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{R}|_{-\frac{\nu}{2}} |\boldsymbol{\Sigma}|_{\frac{\nu}{2}} \left| (\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) + \mathbf{Z}^{-1})^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (502)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{n_i/2}}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \left| (\text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) + \mathbf{Z}^{-1})^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (503)$$

$$= \frac{\Gamma_p((\boldsymbol{\nu} + \mathbf{n})/2)}{\Gamma_p(\overleftarrow{\boldsymbol{\nu}}/2)\Gamma_p(\mathbf{n}/2) \prod_{i=1}^p (m_i^{i\mathbf{R}^{ii}})^{\nu_i/2}} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|_{-\frac{\nu}{2}} \left| \left(\mathbf{I} + \text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}})^{-\frac{1}{2}} \mathbf{Z}^{-1} \text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}})^{-\frac{1}{2}} \right)^{-1} \right|_{\frac{\nu+\mathbf{n}}{2}} \quad (504)$$

For the expected value we have due to independence

$$\mathbb{E} \left[\mathbf{B} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \mathbf{B}^\top \right] = \mathbb{E} \left[\mathbf{B} \text{dg}(\mathbf{m}^{i\mathbf{R}^{ii}}) \mathbf{B}^\top \right], \quad (505)$$

where $\mathbf{m}^{i\mathbf{R}^{ii}}$ is given in (292). Denote

$$\mathbf{T} = \mathbf{B} (\mathbf{m}^{i\mathbf{R}^{ii}})^{1/2}, \quad (506)$$

i.e.

$$\mathbf{T} = \begin{bmatrix} \sqrt{\chi_{n_1-1+1}^2} \sqrt{m_1^{r_1}} & 0 & \dots & 0 & 0 \\ \mathcal{N}(0, 1) \sqrt{m_1^{r_1}} & \sqrt{\chi_{n_2-2+1}^2} \sqrt{m_2^{r_2}} & \ddots & 0 & 0 \\ \mathcal{N}(0, 1) \sqrt{m_1^{r_1}} & \mathcal{N}(0, 1) \sqrt{m_2^{r_2}} & \ddots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \mathcal{N}(0, 1) \sqrt{m_1^{r_1}} & \mathcal{N}(0, 1) \sqrt{m_2^{r_2}} & \ddots & \sqrt{\chi_{n_{p-1}-(p-1)+1}^2} \sqrt{m_{p-1}^{r_{p-1}}} & 0 \\ \mathcal{N}(0, 1) \sqrt{m_1^{r_1}} & \mathcal{N}(0, 1) \sqrt{m_2^{r_2}} & \dots & \mathcal{N}(0, 1) \sqrt{m_3^{r_3}} & \sqrt{\chi_{n_p-p+1}^2} \sqrt{m_p^{r_p}} \end{bmatrix}, \quad (507)$$

with elements $\mathbf{T}_{ij} = \mathbf{B}_{ij} \sqrt{m_j^{r_j}}$. The (i, j) element of $\mathbf{R} = \mathbf{T}\mathbf{T}^\top$ is

$$\mathbf{R}_{i,j} = \sum_{k=1}^p \mathbf{T}_{ik} (\mathbf{T})_{kj}^\top = \sum_{k=1}^p \mathbf{T}_{ik} \mathbf{T}_{jk} = \sum_{k=1}^p m_k^{r_k} \mathbf{B}_{ik} \mathbf{B}_{jk}, \quad (508)$$

which for $i \neq j$ we have

$$\mathbb{E} [\mathbf{R}_{i,j}] = \sum_{k=1}^p m_k^{r_k} \mathbb{E} [\mathbf{B}_{ik} \mathbf{B}_{jk}] = \sum_{k=1}^p m_k^{r_k} \mathbb{E} [\mathbf{B}_{ik}] \mathbb{E} [\mathbf{B}_{jk}] = 0, \quad (509)$$

because of independence of the elements in \mathbf{B} and the fact that at least one of the elements in each summand is mean zero. Furthermore, for $i = j$ we have

$$\mathbb{E} [\mathbf{R}_{i,i}] = \sum_{k=1}^p m_k^{r_k} \mathbb{E} [\mathbf{B}_{ik}^2] = \sum_{k \leq i} m_k^{r_k} \mathbb{E} [\mathbf{B}_{ik}^2], \quad (510)$$

with

$$\mathbb{E} [\mathbf{B}_{ik}^2] = \begin{cases} 1, & \text{for } i \neq k \\ n_k - k + 1 & \text{for } i = k. \end{cases} \quad (511)$$

Thus the elements of $\mathbb{E}_{i^{\mathcal{F}^{\mathcal{R}^i}}}[\mathbf{R}] = \text{dg}(\mathbf{m}^{i^{\mathcal{F}^{\mathcal{R}^i}}})$ are given by

$$\mathbb{E}[\mathbf{R}_{1,1}] = (n_1 - 1 + 1)m_1^{i^{\mathcal{R}^i}}, \quad (512)$$

$$\mathbb{E}[\mathbf{R}_{2,2}] = m_1^{i^{\mathcal{R}^i}} + (n_2 - 2 + 1)m_2^{i^{\mathcal{R}^i}}, \quad (513)$$

$$\mathbb{E}[\mathbf{R}_{2,2}] = m_1^{i^{\mathcal{R}^i}} + m_2^{i^{\mathcal{R}^i}} + (n_3 - 3 + 1)m_3^{i^{\mathcal{R}^i}}, \quad (514)$$

$$\vdots \quad (515)$$

or

$$m_i^{i^{\mathcal{R}^i}} = \sum_{j=1}^{i-1} m_j^{i^{\mathcal{R}^i}} + (n_i + i - 1)m_i^{i^{\mathcal{R}^i}} \quad (516)$$

or more precisely

$$m_i^{i^{\mathcal{R}^i}} = \begin{cases} n_1 m_1^{i^{\mathcal{R}^i}}, & \text{for } i = 1 \\ \sum_{j=1}^{i-1} m_j^{i^{\mathcal{R}^i}} + (n_i + i - 1)m_i^{i^{\mathcal{R}^i}}, & \text{for } i > 1, \end{cases} \quad (517)$$

which for $n_i = n$ and $n_i = n$ for all i equals $\frac{n}{\nu-p-1}$.

For the score w.r.t. Σ start from equation (496), such that

$$\frac{\partial \log p_{\mathcal{I}R^{\nu}}(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} = \frac{\partial \log |\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} + \frac{\partial \log |(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}|_{\frac{\boldsymbol{\nu} + \mathbf{n}}{2}}}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} \quad (518)$$

$$= \frac{\partial \log |\boldsymbol{\Omega}|_{-\frac{\mathbf{n}}{2}}}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} + \frac{\partial \log |(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}|_{\frac{\boldsymbol{\nu} + \mathbf{n}}{2}}}{\partial \text{vech}((\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1})^{\top}} \frac{\partial \text{vech}((\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1})}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} \quad (519)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \right)^{\top} \mathbf{G} + \frac{1}{2} \text{vec} \left(\mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-\top} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-1} \right)^{\top} \quad (520)$$

$$\times \frac{\partial \text{vech}((\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1})}{\partial \text{vech}(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{\top}} \frac{\partial \text{vech}(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})}{\partial \text{vech}(\boldsymbol{\Omega})^{\top}} \quad (521)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \right)^{\top} \mathbf{G} + \frac{1}{2} \text{vec} \left(\mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-\top} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-1} \right)^{\top} \quad (522)$$

$$\times (-1) \mathbf{G}^{+} \left((\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1} \otimes (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1} \right) \mathbf{G} (-1) \mathbf{G}^{+} (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) \mathbf{G} \quad (523)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \right)^{\top} \mathbf{G} + \frac{1}{2} \text{vec} \left(\mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-\top} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-1} \right)^{\top} \quad (524)$$

$$\times \mathbf{G}^{+} \left((\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1} \boldsymbol{\Omega}^{-1} \otimes (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1} \boldsymbol{\Omega}^{-1} \right) \mathbf{G} \quad (525)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \right)^{\top} \mathbf{G} \quad (526)$$

$$+ \frac{1}{2} \text{vec} \left(\boldsymbol{\Omega}^{-1} (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-\top} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{-1} (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1}) \right) \quad (527)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \right)^{\top} \mathbf{G} \quad (528)$$

$$+ \frac{1}{2} \text{vec} \left(\boldsymbol{\Omega}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^{\top} \boldsymbol{\Omega}^{-1} \right)^{\top} \mathbf{G}. \quad (529)$$

Thus using Lemma (7.14) we have

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\partial \log p_{i^{\mathbf{R}''}}(\mathbf{R}|\boldsymbol{\Omega}, \mathbf{n}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \frac{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1} \mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (530)$$

$$= -\frac{1}{2} \text{vec} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} - \boldsymbol{\Omega}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \boldsymbol{\Omega}^{-1} \right)^\top \mathbf{G} \quad (531)$$

$$\times \frac{\partial \text{vech}(\mathbf{C} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1} \mathbf{C}^\top)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (532)$$

$$= -\text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril}(\mathbf{X}\mathbf{C}) \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1} \right) \mathbf{C}^{-1} \right)^\top \mathbf{G} \quad (533)$$

with

$$\mathbf{X}\mathbf{C} = \mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \mathbf{C}_{\boldsymbol{\Omega}}^{-1} \mathbf{C} - \boldsymbol{\Omega}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \boldsymbol{\Omega}^{-1} \mathbf{C} \quad (534)$$

$$= \mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{1/2} - \boldsymbol{\Omega}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}}), \quad (535)$$

such that

$$\text{tril}(\mathbf{X}\mathbf{C}) \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1} \quad (536)$$

$$= \text{tril} \left(\mathbf{C}_{\boldsymbol{\Omega}}^{-\top} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1/2} - \boldsymbol{\Omega}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \mathbf{C}^{-\top} \right) \quad (537)$$

$$= \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{1/2} \text{dg}(\mathbf{n}) \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}})^{-1/2} - \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}}) \mathbf{C}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \right) \quad (538)$$

$$= \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) - \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{i^{\mathbf{R}''}}) \mathbf{C}^{-1} \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}} \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_{(\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}}^\top \mathbf{C}^{-\top} \right) \quad (539)$$

and finally

$$\frac{\log p(\mathbf{R}|\boldsymbol{\Sigma}, \boldsymbol{\nu})}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (540)$$

$$= -\text{vec} \left(\mathbf{C}^{-\top} \Phi \left(\mathbf{C}^\top \text{tril} \left(\mathbf{C}^{-\top} \text{dg}(\mathbf{n}) - \mathbf{C}^{-\top} \text{dg}(\mathbf{m}^{iR'}) \mathbf{C}^{-1} \mathbf{C}_B \text{dg}(\mathbf{n} + \boldsymbol{\nu}) \mathbf{C}_B^\top \mathbf{C}^{-\top} \right) \right) \mathbf{C}^{-1} \right)^\top \mathbf{G}, \quad (541)$$

where $\mathbf{B} = (\boldsymbol{\Omega}^{-1} + \mathbf{R}^{-1})^{-1}$. □

7.7.11 Matrix-F

Theorem 7.15. *Let*

$$\mathbf{R} = \frac{\nu - p - 1}{n} \mathbf{C} \bar{\mathbf{B}}^{-\top} \underline{\mathbf{B}} \underline{\mathbf{B}}^{\top} \bar{\mathbf{B}}^{-1} \mathbf{C}^{\top} \quad (542)$$

$$= \frac{\nu - p - 1}{n} \mathbf{C} \underline{\mathbf{B}} \bar{\mathbf{B}}^{-\top} \bar{\mathbf{B}}^{-1} \underline{\mathbf{B}}^{\top} \mathbf{C}^{\top}, \quad (543)$$

then \mathbf{R} is said to follow a standardized matrix-variate F distribution denoted by $\mathbf{R} \sim \mathcal{F}(\boldsymbol{\Sigma}, n, \nu)$. The probability density function of \mathbf{R} is

$$p(\mathbf{R} | \boldsymbol{\Sigma}, n, \nu) = \left(\frac{n}{\nu - p - 1} \right)^{pn/2} \frac{\Gamma_p((n + \nu)/2)}{\Gamma_p(n/2) \Gamma_p(\nu/2)} |\boldsymbol{\Sigma}|^{-\frac{n}{2}} |\mathbf{R}|^{\frac{n-p-1}{2}} \left| \mathbf{I}_p + \frac{n}{\nu - p - 1} \boldsymbol{\Sigma}^{-1} \mathbf{R} \right|^{-\frac{n+\nu}{2}} \quad (544)$$

$$= \left(\frac{\nu - p - 1}{n} \right)^{\nu n/2} \frac{\Gamma_p((n + \nu)/2)}{\Gamma_p(n/2) \Gamma_p(\nu/2)} |\boldsymbol{\Sigma}|^{\frac{\nu}{2}} |\mathbf{R}|^{\frac{n-p-1}{2}} \left| \frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right|^{-\frac{n+\nu}{2}} \quad (545)$$

$$= \frac{\Gamma_p((n + \nu)/2)}{\Gamma_p(n/2) \Gamma_p(\nu/2)} |\boldsymbol{\Omega}|^{\frac{\nu}{2}} |\mathbf{R}|^{\frac{n-p-1}{2}} |\boldsymbol{\Omega} + \mathbf{R}|^{-\frac{n+\nu}{2}}, \quad (546)$$

where $\boldsymbol{\Omega} = \frac{\nu - p - 1}{n} \boldsymbol{\Sigma}$. The expected value $\mathbb{E}[\mathbf{R}]$ obtains as

$$\mathbb{E}[\mathbf{R}] = \boldsymbol{\Sigma} = \frac{n}{\nu - p - 1} \boldsymbol{\Omega} \quad (547)$$

the score w.r.t. $\boldsymbol{\Sigma}$ is

$$\nabla = \frac{1}{2} \mathbf{G}^{\top} \text{vec} \left(\nu \boldsymbol{\Sigma}^{-1} - (\nu + n) \left(\boldsymbol{\Sigma} + \frac{n}{\nu - p - 1} \mathbf{R} \right)^{-1} \right) \quad (548)$$

and the Fisher information matrix w.r.t. $\boldsymbol{\Sigma}$ is given by

$$\mathcal{I} = . \quad (549)$$

Proof. Recall that the stochastic representations above are equal to the ones of the standardized F-Riesz I and standardized inverse F-Riesz II distribution, respectively, by setting $n_i = n$ and $\nu_i = \nu$ for all i . Next we show, that they both yield the same probability density function for \mathbf{R} and are thus equivalent. For the probability density function of the first stochastic representation start from the standardized F-Riesz I

probability density function to get

$$p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu) = \left(\frac{n}{\nu - p - 1}\right)^{pn/2} \frac{\Gamma_p((n + \nu)/2)}{\Gamma_p(n/2)\Gamma_p(\nu/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{\frac{n}{2}} \left| \mathbf{I} + \frac{n}{\nu - p - 1} \mathbf{Z} \right|^{-\frac{n+\nu}{2}}. \quad (550)$$

Now, starting from the standardized inverse F-Riesz *II* probability density function we have

$$p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu) = \left(\frac{n}{\nu - p - 1}\right)^{pn/2} \frac{\Gamma_p((\nu + n)/2)}{\Gamma_p(\nu/2)\Gamma_p(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{-\frac{\nu}{2}} \left| \left(\frac{n}{\nu - p - 1} + \mathbf{Z}^{-1}\right)^{-1} \right|^{\frac{\nu+n}{2}} \quad (551)$$

$$= \left(\frac{n}{\nu - p - 1}\right)^{pn/2} \frac{\Gamma_p((\nu + n)/2)}{\Gamma_p(\nu/2)\Gamma_p(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{-\frac{\nu+n}{2}} |\mathbf{Z}|^{\frac{n}{2}} \left| \frac{n}{\nu - p - 1} + \mathbf{Z}^{-1} \right|^{-\frac{\nu+n}{2}} \quad (552)$$

$$= \left(\frac{n}{\nu - p - 1}\right)^{pn/2} \frac{\Gamma_p((\nu + n)/2)}{\Gamma_p(\nu/2)\Gamma_p(n/2)} |\mathbf{R}|^{-\frac{p+1}{2}} |\mathbf{Z}|^{\frac{n}{2}} \left| \frac{n}{\nu - p - 1} \mathbf{Z} + \mathbf{I} \right|^{-\frac{\nu+n}{2}}, \quad (553)$$

which is the same probability density function as in (550). Thus both stochastic representations are equivalent.

For the score we have start from (479) to get

$$\frac{\partial \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Omega})^\top} = \frac{1}{2} \text{vec} \left(\frac{n\nu}{\nu - p - 1} \boldsymbol{\Sigma}^{-1} - (\nu + n) \left(\frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right)^{-1} \right)^\top \mathbf{G}, \quad (554)$$

such that

$$\frac{\partial \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma})^\top} = \frac{\partial p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Omega})^\top} \frac{\partial \text{vech}(\boldsymbol{\Omega})}{\partial \text{vech}(\boldsymbol{\Sigma})} \quad (555)$$

$$= \frac{1}{2} \text{vec} \left(\frac{n\nu}{\nu - p - 1} \boldsymbol{\Sigma}^{-1} - (\nu + n) \left(\frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right)^{-1} \right)^\top \mathbf{G} \frac{\nu - p - 1}{n} \quad (556)$$

$$= \frac{1}{2} \text{vec} \left(\nu \boldsymbol{\Sigma}^{-1} - (\nu + n) \left(\boldsymbol{\Sigma} + \frac{n}{\nu - p - 1} \mathbf{R} \right)^{-1} \right)^\top \mathbf{G}. \quad (557)$$

For the Fisher information matrix we have

$$\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma}) \partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (558)$$

$$= \frac{\nu}{2} \frac{\partial^2 \log |\boldsymbol{\Sigma}|}{\partial \text{vech}(\boldsymbol{\Sigma}) \partial \text{vech}(\boldsymbol{\Sigma})^\top} - \frac{n + \nu}{2} \frac{\partial^2 \log \left| \frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right|}{\partial \text{vech}(\boldsymbol{\Sigma}) \partial \text{vech}(\boldsymbol{\Sigma})^\top} \quad (559)$$

$$\begin{aligned} &= -\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad + \frac{n + \nu}{2} \left(\frac{\nu - p - 1}{n} \right)^2 \mathbf{G}^\top \left(\left(\frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right)^{-1} \otimes \left(\frac{\nu - p - 1}{n} \boldsymbol{\Sigma} + \mathbf{R} \right)^{-1} \right) \mathbf{G} \end{aligned} \quad (560)$$

$$\begin{aligned} &= -\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad + \frac{n + \nu}{2} \left(\frac{\nu - p - 1}{n} \right)^2 \mathbf{G}^\top \left((\boldsymbol{\Omega} + \mathbf{R})^{-1} \otimes (\boldsymbol{\Omega} + \mathbf{R})^{-1} \right) \mathbf{G} \end{aligned} \quad (561)$$

$$\begin{aligned} &= -\frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad + \frac{n + \nu}{2} \left(\frac{\nu - p - 1}{n} \right)^2 \mathbf{G}^\top \left(\mathbf{C}_\Omega^{-\top} \otimes \mathbf{C}_\Omega^{-\top} \right) \left(\left(\mathbf{I} + \mathbf{C}_\Omega^{-1} \mathbf{R} \mathbf{C}_\Omega^{-\top} \right)^{-1} \otimes \left(\mathbf{I} + \mathbf{C}_\Omega^{-1} \mathbf{R} \mathbf{C}_\Omega^{-\top} \right)^{-1} \right) \left(\mathbf{C}_\Omega^{-1} \otimes \mathbf{C}_\Omega^{-1} \right) \end{aligned} \quad (562)$$

Now, $\mathbf{Z}_{Kollo} = \mathbf{C}_\Omega^{-1} \mathbf{R} \mathbf{C}_\Omega^{-\top}$ follows a matrix F distribution with scale matrix \mathbf{I} as defined in Theorem 2.4.9. of Kollo and Rosen 2005. They derive on p. 265,

$$\mathbb{E} \left[\left(\left(\mathbf{I} + \mathbf{C}_\Omega^{-1} \mathbf{R} \mathbf{C}_\Omega^{-\top} \right)^{-1} \otimes \left(\mathbf{I} + \mathbf{C}_\Omega^{-1} \mathbf{R} \mathbf{C}_\Omega^{-\top} \right)^{-1} \right) \right] \quad (563)$$

$$= \left(c_3 \mathbf{I} + c_4 \mathbf{K}_{pp} + c_4 \text{vec}(\mathbf{I}) \text{vec}(\mathbf{I})^\top \right) \quad (564)$$

$$= \left((c_3 - c_4) \mathbf{I} + c_4 (\mathbf{I} + \mathbf{K}_{pp}) + c_4 \text{vec}(\mathbf{I}) \text{vec}(\mathbf{I})^\top \right) \quad (565)$$

$$= \left((c_3 - c_4) \mathbf{I} + 2c_4 \mathbf{G} \mathbf{G}^\top + c_4 \text{vec}(\mathbf{I}) \text{vec}(\mathbf{I})^\top \right), \quad (566)$$

with according to their p. 263

$$c_4 = \frac{n-p-1}{(n+\nu-1)(n+\nu+2)} \left(\left(n-p-2 + \frac{1}{n+\nu} \right) c_2 - \left(1 + \frac{n-p-1}{n+\nu} \right) c_1 \right), \quad (567)$$

$$c_3 = \frac{n-p-1}{n+\nu} ((n-p-2)c_2 - c_1) - (n+\nu+1)c_4, \quad (568)$$

$$c_2 = \frac{n(\nu-p-2) + n^2 + n}{(\nu-p)(\nu-p-1)(\nu-p-3)}, \quad (569)$$

$$c_1 = \frac{n^2(\nu-p-2) + 2n}{(\nu-p)(\nu-p-1)(\nu-p-3)}. \quad (570)$$

Thus

$$\mathcal{I} = \mathbb{E} \left[\frac{\partial^2 \log p(\mathbf{R}|\boldsymbol{\Sigma}, n, \nu)}{\partial \text{vech}(\boldsymbol{\Sigma}) \partial \text{vech}(\boldsymbol{\Sigma})^\top} \right] \quad (571)$$

$$\begin{aligned} &= \frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad - \frac{n+\nu}{2} \left(\frac{\nu-p-1}{n} \right)^2 \mathbf{G}^\top \left(\mathbf{C}_\Omega^{-\top} \otimes \mathbf{C}_\Omega^{-\top} \right) \left((c_3 - c_4) \mathbf{I} + 2c_4 \mathbf{G} \mathbf{G}^\top + c_4 \text{vec}(\mathbf{I}) \text{vec}(\mathbf{I})^\top \right) (\mathbf{C}_\Omega^{-1} \otimes \mathbf{C}_\Omega^{-1}) \end{aligned} \quad (572)$$

$$\begin{aligned} &= \frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad - \frac{n+\nu}{2} \left(\frac{\nu-p-1}{n} \right)^2 \mathbf{G}^\top \left((c_3 - c_4) (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) + 2c_4 \mathbf{G} \mathbf{G}^\top (\boldsymbol{\Omega}^{-1} \otimes \boldsymbol{\Omega}^{-1}) + c_4 \text{vec}(\boldsymbol{\Omega}^{-1}) \text{vec}(\boldsymbol{\Omega}^{-1})^\top \right) \end{aligned} \quad (573)$$

$$\begin{aligned} &= \frac{\nu}{2} \mathbf{G}^\top (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) \mathbf{G} \\ &\quad - \frac{n+\nu}{2} \mathbf{G}^\top \left((c_3 - c_4) (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + 2c_4 (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) + c_4 \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G} \end{aligned} \quad (574)$$

$$= \frac{1}{2} \mathbf{G}^\top \left((\nu - (n+\nu)(c_3 + c_4)) (\boldsymbol{\Sigma}^{-1} \otimes \boldsymbol{\Sigma}^{-1}) - (n+\nu)c_4 \text{vec}(\boldsymbol{\Sigma}^{-1}) \text{vec}(\boldsymbol{\Sigma}^{-1})^\top \right) \mathbf{G}. \quad (575)$$

□

Commented out is the proof that an inverse matrix-F distribution with $\boldsymbol{\Sigma}^{-1}$ expectation is again a matrix-F distribution with $\boldsymbol{\Sigma}$ expectation and switched degree of freedoms. For the covariance matrix use Kollo and Rosen 2005, Theorem 2.4.15. together with (??.
